This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

TEXT BOOK OF GUNNERY.

PART I.

In the following pages of Part I (after the definitions have been given) the subject of Gunnery is considered in the order which naturally suggests itself, in the two parts in which it may be divided.

First, Exterior Ballistics, in which the motion of the projectile is considered after it has received its initial velocity of projection, and the projectile is moving freely under the influence of gravity and the resistance of the air, and it is required to determine the conditions so as to hit a certain object.

Secondly, Interior Ballistics, in which the pressure of the powder gas in the bore of the gun is analysed, and the investigation carried out of the requisite charge of powder to secure the initial velocity of the projectile; and in which the calculations are made of the strength of the various parts of the gun required to withstand the pressure at all parts of the bore.

The more mathematical parts of gunnery are resumed and completed in Part II.

Fig. 1.

Digitized by Google

CHAPTER I.—DEFINITIONS AND UNITS.

The **axis of the piece** is the straight line passing down the centre line of the bore.

The **axis of the trunnions** is the straight line passing through the centre of the trunnions, at right angles to the axis of the piece.

The **calibre** is the diameter of the bore in inches measured across the lands.

The **line of sight** is the straight line passing through the sights of the piece and the point aimed at.

The **angle of sight** is the angle which the line of sight makes with the horizontal plane (S, fig. 1).

When the line of sight slopes downwards, as in fig. 1, A, for instance, in firing at a sea-target, the angle of sight is usually called the **Angle of Depression.**

The **line of departure** is the direction in which the shot is moving on leaving the gun; or, in other words, a tangent to the trajectory at the muzzle.

The **angle of departure** is the angle which the line of departure makes with a horizontal plane (D, fig. 1).

The **trajectory** is the curve described by the C.G. (centre of gravity) of the shot in flight (*i.e.*, the curved line GT in fig. 1, A, B).

Range is the distance GT from the muzzle of the gun G to the intersection T of the trajectory with the line of sight.

The **plane of sight and departure** is the vertical plane passing through the lines of sight and departure respectively.

Drift is the deflection of the projectile from the vertical plane of departure due to the rotation imparted by the rifling of the gun. It is sometimes termed Deviation.

The **quadrant angle** is the angle (Q, fig. 1) which the axis of the piece, when laid, makes with the horizontal plane.

It is termed quadrant *elevation* or *depression* (Q.E. or Q.D.), according as the piece is laid above or below the horizontal plane; the term *depressed fire* means that a piece is fired at a quadrant angle of depression (Q.D.).

The **angle of tangent elevation** (T.E.), is the angle between the axis of the gun and the line of sight (T, fig. 1).

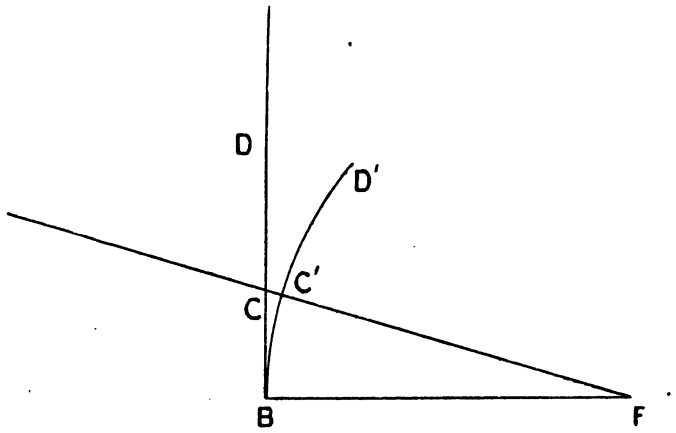
F is the point of the foresight and B is the backsight when the gun's axis is horizontal and laid point blank (see p. 4).

With centre F and radius FB ($= r$ inches) describe an arc BC′D′ and draw BCD a tangent to the arc. If the angle BFC′ = 15° and FC′ be produced to C, then BC subtends an angle of 15° at the foresight, and on the backsight 15° will be marked at C, because BC subtends 15° at F; the backsight BCD is generally called the tangent sight.

Suppose 15° of tangent elevation is given to the gun, it means

Digitized by Google

that the tangent scale is elevated up by a length BC which subtends 15° at F; and similarly for any other angle of tangent elevation.



The angle (S) made by the line of sight with the horizon must be added or subtracted to obtain the *quadrant angle* of elevation or depression from the *tangent angle*; subtracted in fig. 1, A, added in fig. 1, B.

The **angle of projection** is the angle between the line of departure and the line of sight (P, fig. 1).

Jump is the angle between the line of departure and the axis of the gun before firing (J, fig. 1).

The **angle of descent** is the angle which a tangent to the trajectory at the point of impact makes with the line of sight (β, fig. 1).

The **angle of arrival** is the angle which a tangent to the trajectory makes with the horizontal plane (ω, fig. 1).

The **angle of incidence** is the angle which a tangent to the trajectory at the point of impact makes with the normal to the surface struck (i, fig. 1).

Angles are measured in *degrees* and *minutes*, the circumference being divided into 360° (degrees), and each degree into 60′ (minutes).

A watch face will serve as a protractor, for measuring angles, each minute of time on the face being 6° of angle, and each hour is 30° of angle.

Angular velocity is measured always in *radians per second;* the *radian* is the name given to the unit of circular measure, an angle subtended by an arc equal to the radius; the radian is thus

$$180 \div \pi = 57°{\cdot}3, \text{ or } 3438'.$$

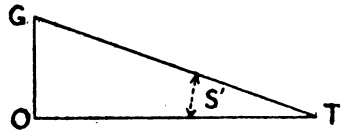
$$\therefore 1 \text{ minute} = \tfrac{1}{3438} \text{ of a radian.}$$

Thus, to turn degrees or minutes of angle into radians of circular measure, divide by 57·3 or 3438.

If the line of sight GT in fig. 1, A, slopes down at an angle of sight of S minutes at a range GT of R yards, in consequence of the gun G being h feet above the horizontal line OT through the target T, then, since GO = h feet and GT = R yards = 3R feet.

Digitized by Google

$\text{Sin S} = \frac{h}{3R}$:



When the angle of sight is small, sin S can be replaced by the circular measure of S′ or by S ÷ 3438; and then

$$\frac{S}{3438} = \frac{h}{3R}, \text{ or } S = 1146\frac{h}{R},$$

the depression-range-finding (D.R.F.) formula, of frequent use in the sequel.

So also for a line of sight sloping upwards as in fig. 1, B.

The gunner's rule that an "inch at 100 yards subtends a minute," and so on in proportion, is equivalent to replacing the number 1146 by 1200, which makes the radian 60° instead of 57°·3, and makes the circumference of a circle three times the diameter.

The following examples may help to define these angles:—

Example 1.—Firing out to sea at a range of 3,000 yards from a battery 300 feet high, the angle of depression

$$S = 1146\frac{300}{3000} = 114'{\cdot}6 = 1° 55'.$$

In the Range Table the angle of elevation is given as 2° 20′, with a jump of + 7′; then (fig. 1, A)

T (tangent elevation) = 2° 20′;
P (angle of projection) = T + J = 2° 27′
D (angle of departure) = P − S = 0° 32′
Q (quadrant elevation) = D − J = 0° 25′.

If the angle of descent is given in the Range Table as 2° 50′, then

β (angle of descent) = 2° 50′,
ω (angle of arrival) = β + S = 4° 45′.

Example 2.—If the angle of tangent elevation is 2° 20′, quadrant angle 4° 15′, and jump 7′, find the angles of departure, of sight, and of projection.

From the definitions and from fig. 1, B,

D (angle of departure) = quadrant angle + jump
= 4° 15′ + 7′
= 4° 22′,
S (angle of sight) = quadrant angle − angle of elevation
= 4° 15′ − 2° 20′
= 1° 55′,
P (angle of projection) = angle of elevation + jump
= 2° 20′ + 7′
= 2° 27′.

Dangerous space is the horizontal distance in which the trajectory would catch a given vertical target; *e.g.*, a shell with a slope of

Digitized by Google

descent of 1 in 10 would catch the broadside of a ship 20 feet out of the water over a distance of 200 feet, which is thus the dangerous space.

Muzzle velocity is the velocity of a projectile on leaving the muzzle, in feet per second; abbreviated in writing to f/s.

Remaining velocity is the velocity at any point of the trajectory.

Striking velocity is the velocity at the point of impact.

PHYSICAL DEFINITIONS.

Force is that which produces, tends to produce, or prevents motion in a body.

The unit of force employed in gunnery is the attraction of the earth on one pound or one ton.

Strictly speaking, it is the tension of a thread or rope, supporting one pound or one ton, thus allowing for a slight discount in the attraction of the earth due to its rotation. This unit of force is a statical or gravitational unit, and it changes slightly, but quite inappreciably for our purposes, for different places on the earth's surface.

Stress is the action of balancing forces; it is estimated in units of force per unit area, generally in pounds or tons per square inch, abbreviated in writing to lb/in.^{2} or tons/in.^{2}

Pressure is a stress tending to prevent the approach of two bodies together.

Tension is a stress tending to prevent the separation of two bodies.

Total thrust or pull P is the product of the stress p and the area A in square inches over which it acts, or

$$P = pA, \qquad p = P/A.$$

Strain is the deformation produced by stress.

Compression is the strain produced in a body by pressure.

Extension is the strain produced in a body by tension.

The **limit of elasticity** of a substance is the least stress producing permanent strain.

For any stress less than the elastic limit, the ratio of stress to strain is found practically to be constant; this ratio is called the **modulus of elasticity**, and denoted by the letter E or M.

$$\text{Thus } E = \frac{\text{stress}}{\text{strain}} = \frac{\text{pressure}}{\text{compression}}, \text{ or } \frac{\text{tension}}{\text{extension}},$$

according as the stress is a pressure or a tension, and E is measured in lbs/in.^{2} or tons/in.^{2} by the ratio of the change of dimension to the original dimension.

Digitized by Google

Under these circumstances, when the stress is removed the strain disappears, and the body returns to its original dimensions.

The **tenacity** of a substance is the breaking tension.

Elasticity and tenacity are expressed in tons on the square inch in practical work.

For gun-steel we may take the modulus of elasticity

$$M = 12{,}500 \text{ tons/in.}^2,$$

and the tenacity as about 34 to 44 tons/in.^{2}, but for the steel wire of a wire gun, the tenacity is as great as 100 tons/in.^{2}.

UNITS.

The **units** employed in gunnery are numerous; this is apt to lead to mistakes in calculations.

The **units of length** are—

Yards for ranges at practice, and in Hadcock's Table X.
Feet in Bashforth's tables, and in expressing the height of any point of the trajectory above plane, as, for instance, the position of the burst of a shell in the air.
Inches are used for calibres of ordnance, diameters of projectiles, and for the distances apart of the marks on the chronograph of Boulengé instrument.
Thousandths of an inch are employed in denoting the shrinkages given to the parts of a gun.

The *units of weight* are—

Tons, cwts., and lb., for ordnance.
Lb. and oz., for projectiles, powder charges, and bursting charges of shells.
Grains, for bullets and powder charges of machine guns and small arms. 7000 grains = 1 lb. avoirdupois.

The metric units of the mètre and kilogramme are universally employed in Continental works on gunnery.

Weight is given in kilogrammes; or in grammes for small weights, such as rifle bullets and charges of powder.

Range is given in mètres (m.), and velocity in mètres per second (m/s).

Work and energy are measured in kilogramme-mètres (kg.-m.), taking $g = 9{\cdot}81$, in mètre-second units.

The calibre of foreign guns is expressed in centimètres (cm.) or millimètres (mm.); and centimètres are converted into inches by multiplying by 0·4, or more accurately by 0·3937, while inches are converted into millimètres by multiplying by 25 or 25·4.

Thus a calibre of 12 centimètres is 4·7 inches, and the 75-mm. field gun and 7·5 mm. rifle have calibres of about 3 and 0·3 inches.

The conversion of other metric measures of length, weight, pressure, energy, velocity, &c., will be found in Table XII.

CHAPTER II.—EXTERIOR BALLISTICS. THE RESISTANCE OF THE AIR, AND THE USE OF THE BALLISTIC TABLES.

SECTION 1.—CONSTRUCTION OF THE BALLISTIC TABLES.

THE first careful experiments on the resistance of the air were carried out by Sir Isaac Newton (in 1687) on spheres of glass, filled with air, water, or mercury, of various weights and diameters, let fall from the dome of St. Paul's Cathedral.

It was assumed that the resistance was proportional to the square of the velocity and the square of the diameter, and then from an observation of the time occupied in falling a given height (220 feet in Newton's experiments in St. Paul's Cathedral) it is possible to infer the resistance of the air from a mathematical formula.

The experiments by Benjamin Robins, in 1743, with his Ballistic Pendulum (Chapter IV), confirmed Newton's results for slow motion, for instance, at velocity below 800 or 900 feet per second (f/s); but for swift motion and velocity above 1200 f/s, Robins found that the resistance of the air was about three times the amount given by Newton's experiments, if calculated on the assumption of the *quadratic* law of resistance, that is, taking the resistance as varying as the square of the velocity.

Later experiments by Hutton in 1775, and at Metz in 1820, carried out with cannon balls against a ballistic pendulum of large size, have also confirmed the law that the resistance of the air to a shot is proportional to the square of the diameter; but no simple mathematical law could be deduced from the experiments which would give the resistance at all velocities, both high and low.

The ballistic pendulum is nowadays partly superseded by electric screens and the chronograph, described in Chapter IV; the passage of the shot through the screens is recorded by an electric signal in the chronograph; the time occupied between the screens is read off, and the velocity and retardation of the shot can then be calculated, and thence the resistance of the air can be inferred.

Elaborate experiments of this nature were carried out by the Rev. F. Bashforth, B.D., in 1865–1870, and again in 1878–1879, and it is on these experiments that the value of the resistance of the air adopted in the construction of the Ballistic Tables has been obtained.

As in Newton's experiments, Mr. Bashforth found that the resistance of the air was proportional to the cross section or to the square of the diameter; so that if p denotes the resistance of the air to a 1-inch projectile, then the resistance to a d-inch projectile, is given by

$$d^2p \text{ pounds.}$$

The value of p in pounds, shown graphically in fig. 3, for projectiles of a standard shape fired under standard conditions is given in Table II for velocities ranging from 100 f/s to 2800 f/s, as deduced from Bashforth's experiments, embodied in the coefficient K given in Table I, the relation between p and K being

$$p = \frac{K}{g}\left(\frac{v}{1000}\right)^3.$$

Digitized by Google

The standard shape adopted in the experiments was that of the service elongated projectile of that period (1865–79), having a cylindrical body and a flat base, and an ogival head struck with a radius of one and a half calibres or diameters, as shown in fig. 1. Thus, take a shot whose diameter across the body is d inches, so that $AB = d''$.

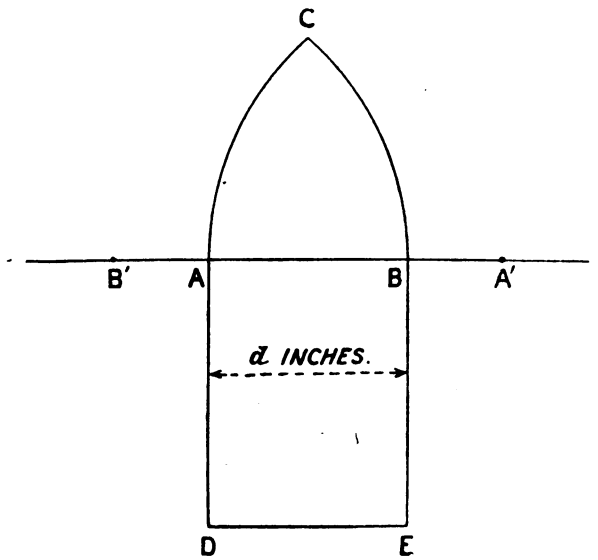
Produce AB both ways, so that $AB' = BA' = \frac{d}{2}$.

Then $AA' = d + \frac{d}{2} = \frac{3d}{2} = BB'$.

With centre A′ and radius $AA' = \frac{3d}{2}$ describe the arc AC.

Similarly with centre B′ and radius BB′ describe the arc BC.

Then the shot CADEB is said to have an ogival head of one and a half calibres or diametres.



To allow for difference in shape, projectiles of the annexed form, shown in fig. 2, were experimented with, and it was found that the

resistance of the air could be represented by

$$\kappa d^2 p \text{ pounds},$$

where κ is a factor depending on the shape of the head and smoothness of the surface, and κ is called the **coefficient of shape.**

Under ordinary conditions the value of κ may vary from 2 in flat headed proof projectiles, and 1·7 for spherical shot, to 0·95 for modern projectiles, and to 0·8 for the magazine rifle bullet.

With the improved steadiness in flight obtained with breech-loading it is found that the resistance is reduced by a factor, σ, called the **coefficient of steadiness,** so that the resistance becomes

$$\kappa\sigma d^2 p \text{ pounds.}$$

On the other hand, the coefficient σ may become greater than unity when the gun is worn, or the projectile imperfectly centered or rotated unsteadily.

Finally it was found that the resistance is proportional to the density of the air, so that if τ denotes the density referred to a certain standard density (534·22 grains per cubic foot in Bashforth's experiments being the weight of 1 cubic foot of air at 62° F. and 30 inches barometer), then the resistance R of the air is given, in pounds, by

$$R = \kappa\sigma\tau d^2 p,$$

and τ is called the **coefficient of tenuity.**

The allowance for tenuity becomes very important with high-angle fire at long ranges, when the shot reaches elevated strata of the air where the density may be halved, or $\tau = \frac{1}{2}$.

But in all accurate records of practice it is important that the barometer and thermometer should be read, upon which the value of τ depends, as given in Table XI.

The product $\kappa\sigma\tau$ of the three coefficients κ, σ, τ is replaced by the letter n, and called the **coefficient of reduction,** so that we write

$$R = nd^2 p.$$

The curve connecting p and v, for the standard projectiles experimented with by Mr. Bashforth, is shown by the curve AA of fig. 3; the curve BB is drawn from the results of Krupp's experiments, where a shot with sharper point was employed; while the curve CC is drawn from the experiments with spherical shot. In the curve AA it is noticed that there are two critical points or sudden bends; one is somewhere near 1100 f/s velocity, which is approximately the velocity of sound and the shot travels through undisturbed air when its velocity is above 1100 f/s; the other bend is near the 2400 f/s velocity; this is the cavitation velocity, that is, the velocity with which air rushes into a vacuum such as may be caused at the base of a projectile which is moving at a high velocity.

Fig. 4 is drawn from a photograph of a bullet in flight, taken by Mr. C. V. Boys; the air waves diverging from the head and the base, and the trail of eddies in the wake of the bullet are very clearly shown, and resemble very closely the waves set up on the surface of water by a swift steamer. (*Nature*, March, 1893.)

Digitized by Google

EXPLANATION OF BALLISTIC TABLE III.

Suppose the projectile is flying horizontally, the effect of gravity being left out of account; the motion is retarded continually by the resistance of the air; and if Δv denotes the loss of velocity, in f/s, in a short interval of time of Δt seconds, then the *average* retardation r is given by

$$r = \frac{\Delta v}{\Delta t}.$$

But by Newton's Second Law of Motion, if the shot weighs w lbs. and the resistance of the air is R pounds, then

$$\frac{r}{g} = \frac{\mathrm{R}}{w}, \quad \text{or} \quad \frac{w}{g} = \frac{\mathrm{R}}{r}.$$

Putting—

$$\mathrm{R} = nd^2p,$$

where p refers to the *average* value in the interval of time Δt, then

$$\frac{\Delta v}{\Delta t} = \frac{\mathrm{R}}{w}g = \frac{nd^2pg}{w},$$

or

$$\Delta t = \frac{w}{nd^2}\,\frac{\Delta v}{pg}.$$

The quantity $\frac{w}{nd^2}$ is very important in the theory of gunnery; it is called the *ballistic coefficient* of the projectile, and denoted by the letter C, so that

$$\mathrm{C} = \frac{w}{nd^2},$$

and then

$$\frac{\Delta t}{\mathrm{C}} = \frac{\Delta v}{pg}.$$

Since p is the same for all projectiles, and g is a constant, then, if we take a constant drop in velocity (say, of 10 f/s, or $\Delta v = 10$),

$$\frac{\Delta v}{pg}$$

is a number *which is the same for all projectiles;* it is denoted by $\Delta\mathrm{T}$, and

$$\Delta\mathrm{T} = \frac{\Delta v}{pg},$$

and this is the time in seconds it takes the unit projectile under standard conditions, for which $\mathrm{C} = 1$, to drop from velocity

$$v + \tfrac{1}{2}\Delta v \text{ to } v - \tfrac{1}{2}\Delta v \text{ f/s},$$

if v denotes the mean velocity in the interval.

Digitized by Google

The number ΔT is calculated numerically once for all, and entered in a column; afterwards the sum of the values of ΔT is made, and entered into a column denoted by T_v, as in Table III, so that $T_V - T_v$ is the time taken by the shot, whose ballistic coefficient C is unity, whilst its velocity falls from V to v f/s.

If the value of C be not unity, then since

$$\frac{\Delta t}{C} = \frac{\Delta T}{1} = \frac{\Delta v}{pg},$$

i.e.,

$$\Delta t = C \,.\, \Delta T,$$

$$\therefore\ t = C\,(T_V - T_v). \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Thus, for example, while the velocity of the shot falls from 1510 to 1500 f/s, the mean velocity in the interval

$$v = 1505;$$

and the corresponding mean value of p from Table II is

$$p = 10{\cdot}3235.$$

Then, with $\Delta v = 10$, $g = 32{\cdot}19$, $\log g = 1{\cdot}5077$, $\log \frac{\Delta v}{g} = \bar{1}{\cdot}4923$.

$\bar{v}$ denotes the mean velocity over an interval.

v.	$\bar{v}$.	p.	$\Delta T = \frac{\Delta v}{pg}$.	T. (In Table III.)
2000	..	..	..	233·4956
	2005	17·2005	0·0181	
2010	..	..	..	233·5137
	2015	17·4100	0·0178	
2020	..	..	..	233·5315
	2025	17·6335	0·0177	
2030	..	..	..	233·5492
	2035	17·8710	0·0174	
2040	..	..	..	233·5666
	2045	18·1095	0·0171	
2050	..	..	..	233·5857

Proportional parts must be employed for unit increments of velocity; and to save this trouble the Table III for T_v has these values interpolated for units in the velocity.

It will be noticed that Table III begins with the tabular number 75·399 against the velocity $v = 100$; this number has no particular signification, but it is made sufficiently large so as not to become negative, supposing the provisional values of the resistance of the air adopted for low velocities should be modified, leaving the numbers for higher velocities unchanged.

Thus it is probable that this number for T against the velocity $v = 100$ was originally put down by Mr. Bashforth as 75, but became modified to 75·399 on a subsequent revision of the table.

Digitized by Google

EXPLANATION OF BALLISTIC TABLE IV.

Next let Δs denote the number of feet described in the interval of time Δt seconds; then

$$\Delta s = v\Delta t,$$

if v denotes the *mean* velocity in the interval; and dividing by C, the ballistic coefficient

$$\frac{\Delta s}{C} = v\frac{\Delta t}{C} = v\Delta T.$$

Denoting this number by ΔS, then

$$\Delta S = v\Delta T,$$

a number which can be tabulated in a Ballistic Table, as it is the same for all projectiles; it is the number of feet which the unit projectile will advance, under standard conditions, while its velocity drops from $v + \frac{1}{2}\Delta v$ to $v - \frac{1}{2}\Delta v$ f/s.

Thus in the interval during which the velocity drops from 1510 to 1500 f/s, we can put

$$v = 1505,$$

and, continuing the numerical calculations,

v.	$\bar{v}$.	$\Delta S = \bar{v}\Delta T$.	S. (In Table IV.)
2000	..	..	45207·1
	2005	36·2	
2010	..	..	45243·3
	2015	35·9	
2020	..	..	45279·2
	2025	35·7	
2030	..	..	45314·9
	2035	35·4	
2040	..	..	45350·3
	2945	35·1	
2050	..	..	45385·4

Any slight discrepancy which may be encountered in the last figure in these calculations may be explained as due to small variations in the density of the air, or to the use of four-figure logarithms; the Slide Rule may be used to perform these calculations with sufficient accuracy.

The calculated values of ΔS are summed, and entered in the first column of Table IV; and the values of S for unit increments of velocity are interpolated afterwards.

Now if a shot goes s feet while the velocity drops V to v f/s,

$$s = C(S_V - S_v). \quad \ldots\ldots\ldots\ldots\ldots\ldots (2)$$

Here again, to avoid negative numbers in case of a revision of Table IV, an arbitrary number S = 1066 is entered against $v = 100$;

Digitized by Google

but as the Table is used for differences $S_V - S_v$, this number does not affect the results; this number 1066 was probably 1000 before a revision of the Table at low velocities.

These two Tables III and IV for T_v and S_v are called Bashforth's Ballistic Tables for Time and Distance (or Space); the numbers T_v and S_v are called the *reduced* time and *reduced* distance; and

$$C\,(T_V - T_v),\quad C\,(S_V - S_v)$$

represent the time taken in seconds and the distance gone in feet, between any initial velocity V and final velocity v, by a shot for which the *ballistic coefficient*

$$C = \frac{w}{nd^2}$$

is unity; for instance a 1-inch 1-pr., or 3-inch 9-pr., of standard shape, under standard conditions, so that $n = 1$.

Digitized by Google

EXPLANATION ON BALLISTIC TABLE V.

A third table, Table V, due to Mr. W. D. Niven, called the *Degree Table*, gives the *deviation* in direction in the vertical plane of a projectile in a flat trajectory, between any initial velocity V and final velocity v f/s.

For if Δi denotes in *radians* (or circular measure) the change of direction, or of slope i, in the trajectory in the time Δt seconds, then resolving normally (as proved in Part II),

$$v \frac{\Delta i}{\Delta t} = g \cos i.$$

When i is small, cos i may be replaced by unity; and

$$\Delta i = \frac{g}{v} \Delta t.$$

But if $\Delta\delta$ denotes the number of degrees in Δi radians,

$$\Delta\delta = \frac{180}{\pi} \Delta i = \frac{180g}{\pi} \frac{\Delta t}{v}.$$

Dividing by the ballistic coefficient C, and denoting $\frac{\Delta\delta}{C}$ by ΔD, then

$$\Delta D = \frac{180g}{\pi} \frac{\Delta T}{v};$$

and ΔD is a number which is the same for all projectiles, being the number of degrees of deviation in direction of motion of the unit projectile, while its velocity drops from $v + \frac{1}{2}\Delta v$ to $v - \frac{1}{2}\Delta v$ f/s, the projectile flying in a nearly horizontal direction.

In continuation of the preceding numerical calculations—

v.	$\bar{v}$.	$\Delta D = \frac{180g}{\pi} \cdot \frac{\Delta T}{v}$.	D. (In Table V.)
2000	..	..	85·2065
	2005	0·0166	
2010	..	..	85·2231
	2015	0·0163	
2020	..	..	85·2394
	2025	0·0162	
2030	..	..	85·2556
	2035	0·0158	
2040	..	..	85·2714
	2045	0·0154	
2050	..	..	85·2868

The summation of the calculated ΔD, and the interpolation of the values of D for unit increments of velocity in Table V, is carried out in the same manner as before in Tables III and IV.

These calculations will serve as a type of those required in a revision of the present Ballistic Tables, consequent on a redetermination by experiment of the value of p with modern projectiles.

Now if the direction of motion changes through δ degrees,

Digitized by Google

while the velocity drops from any initial velocity V to any final velocity v, then

$$\delta = C(D_V - D_v). \quad \ldots\ldots\ldots\ldots\ldots\ldots (3)$$

This Table V is useful in finding angles of departure and descent in direct fire for a given range of X feet.

For if V denotes the initial velocity, and v the final velocity at the end of the range of R yards or X = 3R feet, then

$$\frac{X}{C} = S_V - S_v,$$

or

$$S_v = S_V - \frac{X}{C},$$

whence v is found from Table IV; and then the time of flight T seconds is given by Table III from the formula

$$T = C(T_V - Tv_0).$$

In a flat trajectory the vertical component of the resistance of the air is insensible, so that we may *assume* that the shot takes equal time in going up to the vertex of the trajectory, and in coming down again; in other words the vertex is at the point of *half time*; so that if v_0 denotes the vertex velocity, then

$$\frac{\frac{1}{2}T}{C} = T_V - Tv_0,$$

or

$$T_V - Tv_0 = \tfrac{1}{2}(T_V - T_v)$$

$$Tv_0 = \tfrac{1}{2}(T_V + T_v),$$

whence the corresponding v_0 is found from Table III.

Now if the angles of departure and descent are denoted in degrees by ϕ and β, employing Table V,

$$\phi = C(D_V - Dv_0).$$

$$\beta = C(Dv_0 - D_v).$$

On the *assumption* that the vertical component of the resistance of the air as insensible, suppose the whole time from the gun G to the target at R to be T seconds (see fig. on p. 37), then the time from G to the vertex A is $\frac{T}{2}$ seconds, and at A the shot is travelling in a horizontal direction only, and there is no velocity in a vertical direction, therefore the vertical velocity of the shot at G must have been $\frac{T}{2}g$.

Let P be any point on the trajectory and let t seconds be the time the shot takes to go from G to P, then, if gravity did not act, the shot would, after t seconds from G, have gone a height $\left(\frac{T}{2}g\right)t$ feet above G.

Gravity acting for t seconds will have reduced this height by $\frac{1}{2}gt^2$ feet.

Digitized by Google

Therefore the shot after t seconds from G will have a height

$$\left(\frac{T}{2}gt - \tfrac{1}{2}gt^2\right)$$

feet above G; *i.e.*, height of shot at P will be

$$h \text{ feet} = \frac{T}{2}gt - \tfrac{1}{2}gt^2 = \tfrac{1}{2}gt(T - t) = \tfrac{1}{2}gt\,t',$$

where t' denotes the time down to the ground.

This formula is useful in plotting out the ordinates of a flat trajectory:—

Taking $g = 32$, makes $h = 16t\,t'$;

and at the vertex of the trajectory, where $t = t' = \frac{1}{2}T$,

$$H = \tfrac{1}{8}gT^2 = 4T^2 = (2T)^2;$$

hence the practical rule—the square of double the time of flight in seconds is the height in feet of the vertex of the trajectory.

It will be noticed, however, that the application of Sladen's formula sometimes will give an appearance to the first part of the trajectory of an upward curvature, as is observable with a golf ball.

The approximation is then unsuitable; and the method must be replaced by one in which gravity is first left out of account, and the projectile is supposed to move in the initial direction of projection against the resistance of the air; and afterwards the effect of gravity is supposed to be restored by depressing the projectile a depth $\frac{1}{2}gt^2$ feet, where t denotes the time of flight to any point; this is equivalent to neglecting the vertical component of the resistance compared with its component parallel to the original direction of projection.

To find when Sladen's formula becomes unsuitable we must find when

$$\frac{R}{w} = \cot\phi,$$

or

$$\frac{nd^2p}{w} = \cot\phi,$$

or

$$\tan\phi = \frac{C}{p},$$

the value of p corresponding to the initial velocity V, and ϕ denoting the angle of departure; for greater values of ϕ the method is unsuitable, and the second method must be adopted at the outset.

Explanation of Tables VI and VII.

It is convenient to have a table giving the change in the tangent of the slope of the trajectory, and this is given by the function I, in Table VI, such that, if the slope changes from ϕ to θ in fig. 6, while the velocity changes from V to v,

$$\tan\phi - \tan\theta = C(I_V - I_v).$$

Digitized by Google

In Direct Fire the angles ϕ and θ are small enough for tan ϕ and tan θ, and the circular measure of ϕ and θ to be practically the same, so that the function I can be derived from D by multiplying by the factor

$$\frac{\pi}{180} = 0{\cdot}01745;$$

or if calculated independently, by omitting the factor $\frac{180}{\pi}$ employed in the computation of ΔD, so that

$$\Delta I = g\frac{\Delta T}{v}.$$

The *altitude function* A, invented by Colonel Siacci, has been tabulated by Mr. A. G. Hadcock in Table VII; the theory of this function will be given in Part II; it is required for determining the height y in feet of the shot at any intermediate range of x feet, in High Angle as well as in Direct Fire.

In Direct Fire, the formula required is

$$\frac{y}{x} = \tan\phi - C\left(I_v - \frac{A_v - A_v}{S_v - S_v}\right),$$

where v is the remaining velocity determined by Table IV, from

$$X = C(S_v - S_v).$$

If v denotes the striking velocity at the end of the range of X feet, where $y = 0$ again,

$$\tan\phi = C\left(I_V - \frac{A_v - A_v}{S_v - S_v}\right),$$

which, when the angle of projection ϕ is small, may be replaced by

$$\sin 2\phi = Ca,$$

where

$$a = 2\left(I_v - \frac{A_v - A_v}{S_v - S_v}\right),$$

thus determining the angle ϕ for a range X, when V and C are given.

So, also, from the formula

$$\tan\phi - \tan\theta = C\,[I_V - I_v],$$

when ϕ and θ are small, we may write

$$\tfrac{1}{2}\sin 2\phi - \tfrac{1}{2}\sin 2\theta = C\,[I_V - I_v]$$

i.e.,

$$\sin 2\theta = \sin 2\phi - 2C\,[I_V - I_v],$$
$$= Ca - 2C\,[I_V - I_v],$$

and when the end of the range is considered, θ becomes the angle of descent β.

Digitized by Google

Therefore

$$\sin 2\beta = Ca - 2C\,[I_V - I_v].$$

To save the labour of calculating v and thence a, in terms of V and v, Mr. Hadcock has prepared Table X, a table of double entry, in which the value of a for any range of R yards can be read off corresponding to any initial velocity V, and reduced range $\frac{R}{C}$ yards.

To use Table X, look out on the line for the given velocity V, and in the column corresponding to $\frac{R}{C}$ yards, the number a; then

$$\sin 2\phi = Ca, \text{ or } \tan \phi = \tfrac{1}{2}Ca,$$

with sufficient accuracy, either of which determines ϕ.

Thus, suppose the gun to be 9·2-inch, Mk. IX, for which

$$d = 9{\cdot}2\,;\ n = 0{\cdot}9\,;\ w = 380\,;\ \text{M.V.} = 2700 \text{ f/s},$$

$$C = \frac{w}{nd^2} = \frac{380}{0{\cdot}9 \times (9{\cdot}2)^2} = 5 \text{ nearly.}$$

Then the value of a for this M.V. and for a range R = 4000 yards, that is, for a "reduced range" of $\frac{R}{C}$ or $\frac{4000}{5} = 800$ yards, will be 0·01352; this number is got from Table X., by looking out against the velocity of 2700 f/s and a distance, in yards, of 800.

Proportional parts must be used when the data V and $\frac{R}{C}$ fall between two lines or columns of Table X.

In preparing in this way the column of elevations in a Range Table, it is convenient to calculate ϕ for given muzzle velocity V for every 100 C yards of range, thus taking multiples of 100 in $\frac{R}{C}$; afterwards to interpolate the values of ϕ for the hundreds of yards of actual range; specimen calculations will be given in the sequel.

SECTION 2.—APPLICATION OF THE BALLISTIC TABLES.

In the application of the preceding Ballistic Tables, the notation employed is:—

w = Weight of projectile, in pounds.

d = Diameter of projectile, in inches.

$n = \kappa\sigma\tau$ = Coefficient of reduction.

κ = Coefficient for shape of projectile.

σ = Coefficient for steadiness of projectile.

τ = Coefficient for tenuity or density of air.

$C = \frac{w}{nd^2}$ = Ballistic coefficient.

V = Initial velocity, in feet per second, f/s.

v = Final velocity, in feet per second, f/s.

t = Time of flight, in seconds.

Digitized by Google

(1.) $$t = C\ (T_r - T_v).$$

s = Distance advanced, in feet.

(2.) $$s = C\ (S_r - S_v).$$

ϕ = Initial direction, in degrees, with horizon.

θ = Final direction.

δ = Deviation in direction = $\phi - \theta$.

β = Angle of descent.

(3.) $$\delta = C\ (D_r - D_v).$$

(4.) $$\tan \phi - \tan \theta = C\ (I_r - I_v).$$

In using Table X, in which the velocity v and the range in yards R are given, and it is required to determine ϕ, the initial direction, look out on the line for the given velocity V, and on the column of range corresponding to $\frac{R}{C}$ yards, the number, and denote it by a: then

(5.) $$\sin 2\phi = Ca,$$

which determines ϕ.

(6.) $$\sin 2\beta = Ca - 2C\ [I_V - I_r].$$

In High-angle Fire, V and v must be replaced in the formulas by U and u, called by Colonel Siacci the *pseudo-velocities*, where

(7.) $$U = V \cos \phi \sec \eta;\ u = v \cos \theta \sec \eta.$$

(8.) η = Mean inclination in the arc ϕ to θ.

$= \frac{1}{2}(\phi + \theta)$, approximately.

(9.) $\sec \eta = \frac{i(\phi) - i(\theta)}{\tan \phi - \tan \theta}$, if a closer approximation is desired at high angles of firing; $i(\theta)$ is tabulated in Table VIII.

Now, by the formulas of High-angle Fire

(10.) $$_\phi t_\theta = C\ (T_U - T_u).$$

(11.) $$_\phi x_\theta = C \cos \eta\ (S_U - S_u).$$

(12.) $$\tan \phi - \tan \theta = C \sec \eta\ (I_U - I_u).$$

(13.) $$_\phi\left(\frac{y}{x}\right)_\theta = \tan \phi - C \sec \eta \left(I_U - \frac{A_U - A_u}{S_U - S_u}\right)$$

$$= \tan \phi - C \sec \eta \cdot \frac{a}{2}.$$

In calculating the trajectory over an arc from inclination ϕ to θ, equations (8) and (9) determine η; and V being given, U is found from (7), and then (12) gives I_u and u.

Thence (10), (11), (13), give t, x, and y.

Other useful formulas are—

(14.) If T is whole time of flight, and v_0 is vertex velocity .. .. $\left.\begin{array}{l}\\ \\ \\ \end{array}\right\}$ $\frac{1}{2}T = C(T_V - Tv_0)$ second
or $Tv_0 = \frac{1}{2}(T_V + Tv)$

(15.) The angle of projection $\phi = C(D_V - Dv_0)$.

The angle of descent .. $\beta = C(Dv_0 - Dv)$.

(16.) Height y at any point where T is the whole time .. .. .. $\left.\begin{array}{l}\\ \\ \\ \end{array}\right\}$ $y = \frac{1}{2}gt\ (T - t)$ feet.

(17.) Maximum height .. $H = 4(T)^2 = (2T)^2$ feet.

(18.) Muzzle energy (M.E.) $= \frac{wV^2}{2g \times 2240}$ ft.-tons.

(19.) Striking energy (S.E.) $= \frac{wv^2}{2g \times 2240}$ ft.-tons.

Penetration of wrought iron plate:

(20.) Captain Orde Browne's rough rule $\left.\begin{array}{l}\\ \\ \end{array}\right\}$ $p = \frac{vd}{1000}$ inches.

(21.) For moderate striking velocities $\left.\begin{array}{l}\\ \\ \end{array}\right\}$ $p = 855\,\frac{d^{\frac{3}{4}}}{w^{\frac{1}{2}}}\,p^{97}$.

(22.) For higher velocities. Tresidder's formula $\left.\begin{array}{l}\\ \\ \end{array}\right\}$ $p^2 = \frac{wv^3}{d} \times \frac{1}{\log^{-1} 8{\cdot}8410}$.

The Slide Rule may replace, with ample accuracy, the four-figure logarithms used in the calculations.

N.B.—With modern projectiles and modern armour (20), (21), (22) are replaced by

$$p = \frac{vd}{2200}.$$

See *Problem* 13, p. 39.

Problems on Direct Fire.

Problem 1.—Given C, V, v to find t.

Problem 1.—Find the time it will take for the velocity of the projectiles fired from (*a*) 15-pr. B.L. Mark IV, (*b*) 6-inch B.L. Mark VII ($\frac{1}{3}$ charge), (*c*) 9·2-inch B.L. Mark II ($\frac{3}{4}$ charge) to fall to 1000 f/s, using Table III and

$$t = C\,(T_V - T_v).$$

Data.	*d*.	*w*.	V.	*v*.
(*a*)	3·0	14·0	1581	1000
(*b*)	6·0	100	1570	1000
(*c*)	9·2	380	1531	1000

Note.—Take $n = 0{\cdot}9$ in this and all other examples, if not otherwise stated.

The solution of these problems should be effected by the use of the Slide Rule with sufficient accuracy for practical purposes and in a shorter time than by using logarithms; in any case, even in the simplest problems, the work should be set out in some such form as the following:—

To find t in each case, using logarithms,

$$t = C\,(T_V - T_v).$$

	(*a*.)	(*b*.)	(*c*.)
$\log w$	1·1461	2·0000	2·5798
$\log d^2$	0·9542	1·5563	1·9276
$\log \frac{w}{d^2}$	0·1919	0·4437	0·6522
$\log n$	$\bar{1}$·9542	$\bar{1}$·9542	$\bar{1}$·9542
$\log \frac{w}{nd^2} = \log C$	0·2377	0·4895	0·6980
T_V	232·5472	232·5165	232·4046
$T_v = T_{1000}$	229·5207	229 5207	229·5207
$T_V - T_v$	3·0265	2·9958	2·8839
$\log (T_V - T_v)$	0·4809	0·4766	0·4600
$\log C$	0·2377	0·4895	0·6980
$\log t = \log C\,(T_V - T_v)$	0·7186	0·9661	1·1580
t	5·231	9·249	14·39

Working with a Slide Rule, we have

	(*a*.)	(*b*.)	(*c*.)
$\frac{w}{nd^2} = C$	1·729	3·08	
V	1581	1570	
T_V	232·5472	23	
$T_v = T_{1000}$	229·5207		
$T_V - T_v$	3·0265		
$t = C\,(T_V - T_v)$	5·23		

Digitized by Google

Problem 2.—Given V, C, *t* to find *v*.

Problem 2 —Given V, C, and *t*, to find *v*, from the formula

$$T_v = T_V - \frac{t}{C}.$$

Find the remaining velocity after 15 seconds of the projectiles in Problem 1.

Here $t = 15$, the other data are as in the preceding problem, working by Slide Rule.

	(*a.*)	(*b.*)	(*c.*)
T_V	232·5472	232·5165	232·4046
$\frac{t}{C} = \frac{15}{C}$	8·67	4·858	3·0070
T_v	223·8772	227·6585	229·3976
v	733	884	991 f/s.

Problem 3.—Given *v*, C, *t* to find V.

Problem 3.—Given *v*, C, and *t*, to find V, from the formula

$$T_V = T_v + \frac{t}{C}.$$

Find the muzzle velocities of the following three guns in order that their remaining velocity after 4·8 seconds may be 970 f/s :—

	d.	*w.*
(*a.*) 6-pr. Hotchkiss Q.F.	2·244	6·0
(*b.*) 12-pr. B.L.	3·0	12·5
(*c.*) 8-inch B.L. Howitzer	8·0	276·5

As usual, *n* is taken = 0·9, working by Slide Rule.

	(*a.*)	(*b.*)	(*c.*)
$C = \frac{w}{nd^2}$	1·323	1·543	4·790
$\frac{t}{C} = \frac{4·8}{C}$	3·625	3·11	1·00
$T_v = T_{970}$	229·1014	229·1014	229·1014
$T_V = T_v + \frac{}{C}$	232·7264	232·2114	230·1014
V	1648	1467	1048

V, C, and *v*, to find *s*, from Table IV and the

$s = C (S_V - S_v)$.

at which the remaining velocities of the
1200 f/s.

r data are as in Problem 1.

Digitized by Google

Problem 5.—Given V, C, *s* to find *v*.

The results shown here are got by Slide Rule, and can be verified by using logarithms.

	(*a.*)	(*b.*)	(*c.*)
V	1581	1570	1531
S_V	43523·5	43475·1	43301·7
$S_v = S_{1200}$	41591·9	41591·9	41591·9
$S_V - S_v$	1931·6	1883·2	1709·8
C	1·729	3·08	4·98
$S = C(S_V - S_v)$ ft.	3340	5813	8531
Range in yards $= \frac{S}{3}$	1113	1938	2844

Problem 5.—Given V, C, and *s*, to find *v*, from the formula

$$S_v = S_V - \frac{s}{C}.$$

Find the remaining velocity and time of flight for a range of 1,800 yards for the following guns:—

	d.	*w.*	*n.*	V.
(*a.*) Service rifle.....	0·307	215 grains	0·78	2050
(*b.*) 3-pr. Nordenfelt Q.F....	1·85	3·3 lbs.	1·0	1920
(*c.*) 8-inch B.L.	8·0	180 lbs.	0·9	2000

Note.—The calibre of (*a.*) is 0·303, but the depth of each rifling groove is 0·004, or more than 1 per cent. In such a case it is usual to take *d* as the calibre + the depth of *one* groove.

There are 7,000 grains in one pound avoirdupois.

By Slide Rule:—

	(*a.*)	(*b.*)	(*c.*)
$\frac{w}{nd^2} = C$	0·417	0·964	3·13
V	2050	1920	2000
S_V	45385·4	44908·7	45207·1
$\frac{s}{C} = \frac{1800 \times 3}{C}$	12960·0	5610·0	1725·0
S_v	32425·4	39298·7	43482·1
v	627	961	1572 f/s.

Next to find the times of flight

$$t = C(T_V - T_v).$$

	(*a.*)	(*b.*)	(*c.*)
T_V	233·5837	233·3432	233·4956
T_v	219·9914	228·9678	232·5221
$T_V - T_v$	13·5923	4·3754	0·9735
$t = C(T_V - T_v)$	5·66	4·22	3·05 secs.

Problem 8.—Given C, *v* and *s* to find V.

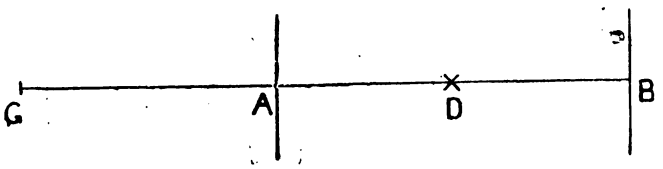
Problem 8.—Given C, v and s to find V from

$$S_V = S_v + \frac{s}{C}.$$

Find the muzzle velocity of the 12-pr. B.L. Mk. IV of 6 cwt. when the time taken by the projectile in passing between two screens 180 feet apart (the first being 50 yards from the muzzle) is

(*a.*) 0·1152 second, with the service projectile,
(*b.*) 0·1174 „ „ flat-headed projectile.

In both cases $\sigma = 0·9$, in (*a.*) $k = 1·0$, and in (*b.*) $k = 1·817$.
What difference in the result of (*b.*) will be caused by taking $k = 2·0$?



Suppose the muzzle of the gun at G, the 1st screen at A and the 2nd one at B, then

GA = 50 yards = 150 feet,
AB = 180 feet.

The velocity of the shot diminishes continuously, but not at a uniform rate from A to B; for purposes of calculation in such problems as this the mean velocity of the shot between A and B is considered to be at D, the mid-point of AB, so that we find the velocity at D by dividing the distance AB by the time taken in going from A to B.

Digitized by Google

Thus velocity at point D $= v = \frac{AB}{t} = \frac{180}{0{\cdot}1152}$ f/s for (*a.*);

$$v = \frac{180}{0{\cdot}1174} \text{ f/s for } (b.).$$

Now,

$$AD = \frac{180}{2} = 90 \text{ feet},$$

hence

$$\text{distance GD} = (3 \times 50 + 90) \text{ feet} = 240 \text{ feet}.$$

The velocity v at D is known, and

$$GD = s = 240,$$

C is calculated, and the muzzle velocity at G is found from

$$S_V = S_v + \frac{s}{C}.$$

	(*a.*)	(*b.*)	(*b'.*)
	$k = 1{\cdot}0$	$k = 1{\cdot}817$	$k = 2{\cdot}0$
	$\tau = 1$	$\tau = 1$	$\tau = 1$
$v = \frac{180}{t}$	1564	1534	1534
$C = \frac{w}{k\sigma\tau d^2}$	1·545	0·849	0·772
$= \frac{12{\cdot}5}{k \times {\cdot}9 \times 1 \times 3^2}$			
$\frac{s}{C} = \frac{240}{C}$	155·5	282·5	310·5
S_v	43448·6	43315·1	43315·1
$S_V = S_v + \frac{s}{C}$	43604·1	43597·6	43625·6
V	1599 f/s	1599 f/s	1604 f/s

The above is worked out by Slide Rule.

Problem 9.—Find the remaining velocity, time of flight, and height of the trajectory of the service rifle at intervals of 125 yards for a range of 1000 yards, using the formula

Problem 9.—Given V for a magazine rifle to plot the trajectory.

$$h = \tfrac{1}{2}gt\,(T - t)$$

for the height.

From Problem 5 we get the data

$$d = 0{\cdot}307 \text{ inch},$$

$$w = \tfrac{211{\cdot}5}{7000} \text{ lb.},$$

$$n = 0{\cdot}78,$$

$$V = 2050.$$

Digitized by Google

Therefore

$$C = \frac{w}{nd^2} = \frac{215}{7000} \cdot \frac{1}{(\cdot 78) \times (\cdot 307)^2} = 0{\cdot}417.$$

To complete the problem, we have to use in succession three formulas

$S = C(S_V - S_v)$ to get remaining velocities,

$t = C(T_V - T_v)$ to get time for various distances,

$h = \frac{1}{2}gt(T - t)$ for the ordinates at various distances.

The annexed scheme of calculation shows a systematic procedure and blank spaces are to be filled in as an exercise.

It will be seen that the greatest height of the trajectory lies between 500 yards and 625 yards, which shows that this highest point is a little beyond the half-way range; also on plotting to scale the curve is much less steep up to the highest point or vertex than from the vertex to the end of the range.

Problem 10.—Given V, C and R to find ϕ, the angle of projection, from Table X., and the formula

Problem 10.—Given V, C, R to find ϕ from formula $\sin 2\phi = Ca$.

$$\sin 2\phi = Ca.$$

Also to find β, the angle of descent from Table VI, and the formula

$$\sin 2\beta = 2C(I_V - I_v) - Ca.$$

Find ϕ and β for the service rifle at intervals of 125 yards up to a range of 1000 yards.

Note.—125 yards is selected because it makes the value of $\frac{R}{C}$ always an exact multiple of 100 yards, thereby avoiding the use of proportional parts in Table X.

We have, from Problem 9,

$$V = 2050,$$
$$C = 0{\cdot}417.$$

V, C being known, we calculate ϕ thus:—

V = 2050 f/s.

Range in yards, R.	$\frac{R}{C}$.	a.	$Ca = \sin 2\phi$ (by slide rule).	2ϕ.	ϕ.

750	1800	0·07404	0·03091	1 46	53·0
875	2100	0·09480	0·03955	2 16	1 8
1000	2400	0·1184	0·0494	2 50	1 25

By a similar scheme we can calculate β, without first knowing ϕ, by Table VI. and

$$\sin 2\beta = 2C(I_V - I_v) - Ca.$$

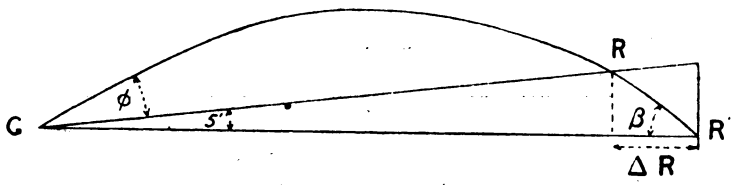
It is advisable in all long series of calculations of this description to plot the results on a large sheet of squared paper, as then not only can numerical errors be at once detected by the irregularity of the curve, but any intermediate values can be read off at once and with sufficient accuracy for most practical purposes.

A short and sufficiently accurate method of obtaining β when ϕ is known for all ranges is

$$\beta' = \frac{5R}{\Delta R},$$

where β is in minutes, R the range, and ΔR the extra range obtained by adding 5 minutes to ϕ (the minutes elevation for range R).



Thus, in triangle GRR′,

$$\frac{R+\Delta R}{R} = \frac{GR'}{GR} = \frac{\sin GRR'}{\sin GR'R} = \frac{\sin(\beta+5)}{\sin\beta} = \frac{\beta+5}{\beta},$$

i.e.,

$$1 + \frac{\Delta R}{R} = 1 + \frac{5}{\beta},$$

or

$$\beta' = \frac{5R}{\Delta R}.$$

Problem 11.—To find loss of range for a reduced muzzle velocity, using formula $\sin 2\phi = Ca$

Problem 11.—The guns in Problem 1 are fired with velocities reduced 50 f/s. Find the errors in range at 1000, 2000 and at 4000 yards caused by using the old tangent scale.

Making use of Table X., ϕ for each range is found thus

$$R_1,\quad \frac{R_1}{C},\quad a,\quad aC,\quad 2\phi,\quad \phi,$$

looking up a for the original velocity.

Then the new value of R is found by reversing the process, thus

$$\phi,\quad 2\phi,\quad aC,\quad a,\quad \frac{R_2}{C},\quad R_2$$

looking up a for the reduced velocity.

Then $R_1 - R_2$ is the required result.

This long process is however needless, since the value of a is the same in each case; this is seen at once because

$$a = \frac{\sin 2\phi}{C}.$$

Digitized by Google

$C = \frac{w}{nd^2}$ is the same for the original and for the reduced velocities.

So ϕ is the same, as stated in the question for both velocities.

Therefore a is the same for both velocities. The procedure is now much shortened, it is

$$R, \quad \frac{R_1}{C}, \quad a, \text{ (for original velocity)} \quad \frac{R_2}{C}, \text{ (for reduced velocity)} \quad R_2, \quad R_1 - R_2.$$

The muzzle velocities for the three guns are 1581, 1570, 1531, but are in this problem taken as 1580, 1570, 1530, and the reduced velocities are 1530, 1520, 1480.

(a.) C = 1·729. M.V. = 1580.

R_1 yards.	$\frac{R_1}{C}$.	a (for V = 1580).	$\frac{R_2}{C}$ (for V = 1530).	R_2.	$R_1 - R_2$.
1000	578	0·02672	547·7	947·5	52·5
2000	1156	0·06325	1106·7	1912	88·0
4000	2312	0·1703	2241·7	3880	120·0

(b.) C = 3·09. M.V. = 1570.

			(for V = 1520).		
1000	324	0·01401	306·0	945	55
2000	648	0·03097	615·0	1900	100
4000	1296	0·07458	1242·4	3840	160

(c.) C = 5·0. M.V. = 1530.

			(for V = 1480).		
1000	200	0·00872	188·2	941·0	59
2000	400	0·01862	377·6	1888·0	112
4000	800	0·04198	760·2	3801·0	199

We thus see at a glance the loss of range in yards for all three guns at the different ranges.

The Slide Rule has been used and for gun (a.) the full working showing proportional parts is given.

To find a, from Table X., for $\frac{R_1}{C} = 578$, V = 1580.

Under velocity of 1580 f/s we have

$$a_{600} = \cdot02790$$
$$a_{500} = \cdot02252$$
$$\text{Difference} = \cdot00538.$$

Digitized by Google

Therefore

$$a_{578} = a_{500} + \cdot00538 \times \tfrac{78}{100} = \cdot02252 + \cdot00420,$$
$$= \cdot02672.$$

Again, given that

$$a = \cdot02672 \text{ and that } V = 1530, \text{ to find } \frac{R_2}{C}$$

We have under the velocity 1530, Table X.,

a_{600}	$= \cdot02969$
a_{500}	$= \cdot02400$
Difference	$= \cdot00569.$

a_x	$= \cdot02672$, where x denotes the unknown $\frac{R_2}{C}$.
a_{500}	$= \cdot02400$
Difference	$= \cdot00272.$

Therefore

$$x \text{ or } \frac{R_2}{C} = 500 + \frac{\cdot00272}{\cdot00569}\,100.$$
$$= 547{\cdot}7 \text{ (by Slide Rule).}$$

Again, for the 2000-yards range,

	V = 1580.		V = 1530.
a_{1200}	$= \cdot06644$	a_{1200}	$= \cdot07037$
a_{1100}	$= \cdot05920$	a_{1100}	$= \cdot06274$
Difference	$= \cdot00724.$	Difference	$= \cdot00763.$

Therefore

$$a_{1156} = \cdot05920 + \tfrac{56}{100} \times \cdot00724$$
$$= \cdot05920 + \cdot00405$$
$$= \cdot06325.$$

a_x	$= \cdot06325$
a_{1100}	$= \cdot06274$
Difference	$= \cdot00051.$

$$x \text{ or } \frac{R_2}{C} = 1100 + 6{\cdot}7 = 1106{\cdot}7.$$

At 4000 yards,

	V = 1580.		V = 1530.
a_{2400}	$= \cdot1803$	a_{2300}	$= \cdot1770$
a_{2300}	$= \cdot1689$	a_{2200}	$= \cdot1655$
Difference	$= \cdot0114.$	Difference	$= \cdot0115.$

$$a_{2312} = \cdot1689 + \tfrac{12}{100} \times \cdot0114$$
$$= \cdot1689 + \cdot00136$$
$$= \cdot 70\,.$$

a_x	$= \cdot1703$
a_{2200}	$= \cdot1655$
Difference	$= \cdot0048.$

$$x \text{ or } \frac{R_2}{C} = 2200 + \tfrac{48}{115} \times 100$$
$$= 2200 + 41{\cdot}7$$
$$= 2241{\cdot}7.$$

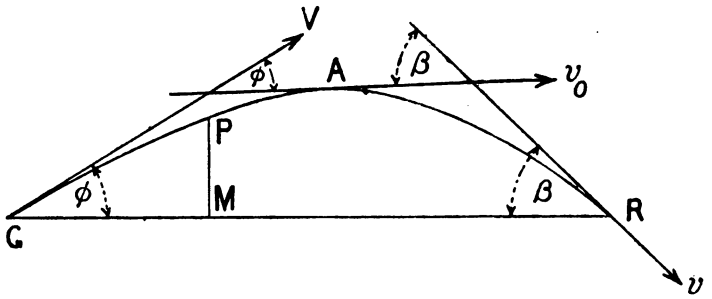
Problem 12.—Using the D_V table (Table V), find ϕ and β for ranges of 2000, 3500 and 6000 yards when using a $\frac{3}{4}$ charge for the 9·2-inch B.L., Mark IX. Given M.V. = 2200, $n = 0{\cdot}9$, C = 5·0.

Compare the values of ϕ with those obtained by using Table X and find the maximum height at each range.

In using Table V, the steps are to find the remaining velocity v

Problem 12.—Given V, C, R, to find angles of projection and descent, using formula $\delta = C\ (D_V - D_v)$.



at the end of each range.

Thence to find the whole time of flight T. The time to the highest point being $\frac{T}{2}$, we can find the velocity v_0 at the vertex.

After this we find ϕ and β at once by using the D_V table.

C=5. $\frac{3}{4}$ charge. M.V.=2200 f/s. R=2000, 3500, 6000 yards.

R	2000	3500	6000
$S_V = S_{2200}$	45877·5		
$\frac{s}{C} = \frac{3 \times R}{5}$	1200·0	2100	3600 feet.

$T_V = T_{2200}$	233·8158	233·8158	233·8158
T_v	233·2207	232·7050	231·6825
$\frac{t}{C} = T_V - T_v$	0·5951	1·1108	2·1333
t	2·9755		
$\frac{1}{2}\frac{t}{C}$	0·2975		
$T_{v_0} = T_V - \frac{1}{2}\frac{t}{C}$	233·5183		
v_0 (velocity at vertex)	2013	1879	1657

Digitized by Google

$D_V = D_{2200}$	85·4885		
D_{v_0}	85·2280		
$\frac{\phi}{C} = D_V - D_{v_0}$	0·2605		
ϕ	1° ·3025 = 1° 18′	2° ·5305 = 2° 32′	5° ·2015 = 5° 12′
D_{v_0}	85·2280		
D_v	84·9435		
$\frac{\beta}{C} = D_{v_0} - D_v$	0·2845		
β	1° ·42 = 1° 25′	2° ·92 = 2° 55′	6° ·70 = 6° 42′
Maximum height, $H = 4t^2$	35·3 ft.	123·0 ft.	454 ft.

Working by Table X., ϕ is obtained as follows :—

R	2000	3500	6000
$\frac{R}{C}$	400	700	1200
a	0·00870	0·01674	0·03489
$aC = \sin 2\phi$	0·04350	0·08370	0·17445
2ϕ	2° 30′	4° 48′	10° 3′
ϕ	1° 15′	2° 24′	5° 1½′

The disagreement between the results is instructive as showing the limitations of Table V.

Problem 13.—To determine $\frac{w}{d^3}$ for various guns.

Problem 13.—Determine the value of $\frac{w}{d^3}$ for each of the following guns :—

From the results of the values so found, show that Krupp's 1896 formula for the penetration of modern hard-face armour,

$$p^2 = \frac{wv^2}{d} \times \frac{1}{\log^{-1} 6{\cdot}3532},$$

can be put into the simpler form

$$p = \frac{vd}{2200}.$$

Digitized by Google

(*a.*) 6-inch B.L., Mk. VII, $w = 100$, $d = 6$.

(*b.*) 9·2-inch B.L., Mk. X, $w = 380$, $d = 9{\cdot}2$.

(*c.*) 12-inch B.L., VIII, IX, $w = 850$, $d = 12$.

(*d.*) 7·5-inch B.L., $w = 200$, $d = 7{\cdot}5$.

The formula may be written

$$p = \left(\frac{w}{d}\right)^{\frac{1}{2}} \frac{v}{1500},$$

since $\log^{-1} 6{\cdot}3532 = 2250000 = (1500)^2$ nearly, that is

$$p = \frac{vd}{1500} \cdot \left(\frac{w}{d^3}\right)^{\frac{1}{2}}.$$

	(*a.*)	(*b.*)	(*c.*)	(*d.*)
$\frac{w}{d^3}$	0·463	0·488	0·49	0·475

When

$$\frac{w}{d^3} = 0{\cdot}46,$$

$$p = \frac{vd}{1500}\left(\frac{w}{d^3}\right)^{\frac{1}{2}} = \frac{vd}{1500 \times 1{\cdot}47} = \frac{vd}{2200} \text{ nearly.}$$

Problem 14.—The projectiles of the following guns

(*a.*) 15-pr. B.L., Mk. IV, $w = 14$ lbs., $d = 3$, $V = 1580$.

(*b.*) 6-inch B.L., VII (half charge), $w = 100$, $d = 6$, $V = 1570$.

(*c.*) 9·2-inch B.L., IX (full charge), $w = 380$, $d = 9{\cdot}2$, $V = 2642$.

Problem 14.—Effect of change in tenuity factor on range of a gun.

are fired when τ (the tenuity factor) $= 1{\cdot}0$ and $0{\cdot}9$.

Find the change in range at every 2,500 yards up to their extreme ranges.

Let the ballistic coefficients when $\tau = 1{\cdot}0$ be C,

and " " " " $\tau = 0{\cdot}9$ " C'.

Then, the same elevation being given at each range,

$$\sin 2\phi = Ca = C'a',$$

$$\therefore \frac{Ca}{C'} = a'.$$

But

$$C = \frac{w}{1 \times d^2}, \quad C' = \frac{w}{{\cdot}9d^2}, \quad \therefore \frac{C}{C'} = 0{\cdot}9.$$

$$\therefore a' = \frac{Ca}{C'} = 0{\cdot}9 \,.\, a.$$

Digitized by Google

The procedure to complete the whole problem is as follows :—

The detail of proportional parts is not shown; it is an excellent practice to verify the work shown either by Slide Rule or by logarithms.

R.	$\frac{R}{C}$.	a.	$a' = \frac{C}{C'}a = 0{\cdot}9a$.	$\frac{R'}{C'}$.	R'.	(R'−R) yards.

Problem 15.—The following is from a paper on "Exterior Ballistics," by Professor G. Forbes, F.R.S. ("Proceedings of the Royal Society," Vol. 74) :—

To make a range table for x per cent. increase of air density diminish each elevation and corresponding range by x per cent. The elevations thus found are correct for the ranges thus found with the new air density. The time of flight is diminished by x per cent. The remaining velocity found in the range table is the same for the new range table at the altered range.

With the usual notation

$$C = \frac{w}{nd^2}$$

v_0 is the velocity at the vertex of the trajectory, v the remaining velocity, X the range in feet.

Suppose the air density increased in the ratio m to 1, let

$$C' = \frac{w}{mnd^2} = \frac{C}{m},$$

and

$$X' = \frac{X}{m},$$

Digitized by Google

so that

$$\frac{X'}{C'} = \frac{X}{C}.$$

Let us now find the elevation for X′ feet.
For a given range X feet

$$S_v = S_V - \frac{X}{C} \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad I,$$

thence

$$t = C\,(T_V - T_v) \ldots\ldots\ldots\ldots\ldots\ldots \quad II.$$

It is assumed that for elevations up to 15° the vertex of trajectory is reached in half the time of flight; hence

$$T_{v_0} = T_V - \frac{\frac{1}{2}t}{C} \quad \ldots\ldots\ldots\ldots\ldots\ldots \quad III,$$

also

$$\phi = C\,(D_V - D_{v_0}) \ldots\ldots\ldots\ldots\ldots\ldots \quad IV,$$

thus for a given range X feet, t, v_0 and ϕ are found.
In I,

$$\frac{X'}{C'} = \frac{X}{C}$$

and V is unchanged. Therefore v remains unchanged, or $v' = v$.
In II,

$$\frac{t'}{t} = \frac{C'}{C} = \frac{1}{m}, \quad \text{or} \quad t' = \frac{t}{m}.$$

Also v'_0 is found from III,

$$T_{v'_0} = T_V - \frac{\frac{1}{2}t'}{C'} = T \quad - \frac{\frac{1}{2}t}{C} = T_{v_0};$$

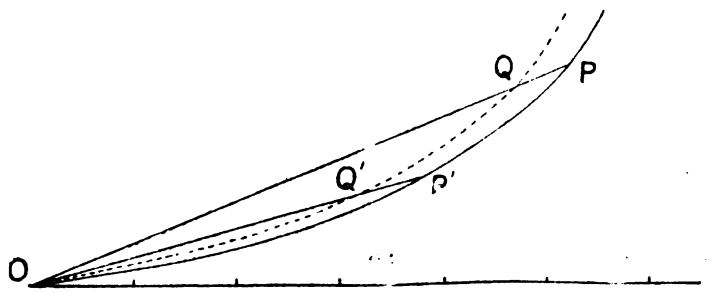
therefore

$$v'_0 = v_0.$$

Again, from IV,

$$\phi' = C'\,(D_V - D_{v'_0})$$
$$= C'\,(D_V - D_{v_0}) = C' \cdot \frac{\phi}{C} = \frac{\phi}{m}.$$

It appears then that if the air density be increased m °/₀, and the range diminished m °/₀, the elevation and time of flight must be diminished m °/₀, but the remaining velocity is the same.



Digitized by Google

Abscissæ represent ranges.
Ordinates represent elevations.
PP′ Range Table elevations at normal air density.
QQ′ " " " with air density increased 10 per cent.
$QP = \frac{1}{11}OP$; $Q'P' = \frac{1}{11}OP'$.

The solution for flat trajectories is extremely neat when stated geometrically.

Draw a curve in which abscissæ are ranges and ordinates are the elevations of the Range Table.

To draw a similar curve for air density increased in the ratio $m : 1$ proceed as follows:—From the origin of co-ordinates O, draw straight lines to points P, P′, &c., on the Range Table curve. In these lines take points Q, Q′, &c., so that

$$\frac{OP}{OQ} = \frac{OP'}{OQ'} = \&c. = m.$$

Then the locus of Q is the new curve.

EXAMPLES.

A.

1. The Range Table for a 6-inch B.L., Mark VII, shows angles of elevation as follows: 3000 yards, 1° 40′; 5000 yards, 3° 33′; 6000 yards, 4° 46′: what will be the Q.E. when the gun is mounted 100 feet above mean sea-level?
2. Certain angles of descent are 1°, 1° 24′, 2° 17′, 4° 24′: find the corresponding slopes of descent.
3. At exactly half tide a gun is known to be 150 feet above the sea-level; the angle of depression to a ship being 50′, find the range.
4. The width of a row of dummies put out is known to be 25 yards, their angular width is observed by the telescopic sight to be 45′: find the range.
5. A 9-feet target is observed from the gun to have an angular height of 5′, another observer makes it 6′: what difference would this make in the calculated range?
6. A ridge of ground, 100 yards distant from a gun, is observed to have an angular height above the horizontal plane of 3° 49′; what is the height of the top of the ridge in feet?

B.

In the following questions the value of n, the coefficient of reduction, is 0·9, unless otherwise stated:—

1. With a 5-inch B.L. Howitzer, find the remaining velocity at 1000 yards range, given M.V. = 782, $w = 50$, $d = 5$ and S is 3000 feet.
2. Find the time of flight of this Howitzer shell over the same range.
3. Find the maximum height of the trajectory.
4. Compare the maximum height with that of the 4·7-inch Q.F., which has a muzzle velocity of 2150 f/s and a time of flight of 1·6 seconds (see Range Table, p. 62) for a 1000 yards range.

Digitized by Google

5. If the first graze of a trial shot from a 4·7-inch Q.F. is observed to occur after 4·3 seconds, the range being 2400 yards, what must be the value of n in this case? (See p. 62.)
6. Calculate the height above the horizontal plane of the 5-inch projectile in Problem (1) at
   (*a.*) The half distance of the range;
   (*b.*) 400 yards from the gun;
   (*c.*) 400 yards short of the target.
7. Plot the 5-inch Howitzer projectile's trajectory for a range of 1000 yards.
8. With the 12-pr. B.L., for which V = 1710 f/s, $w = 12{\cdot}5$ lbs., $d = 3$, find
   (*a.*) The remaining velocity at a range of 2000 yards;
   (*b.*) Find the time of flight;
   (*c.*) Find the angle of descent, the angle of elevation being 2° 38′, and jump 22′;
   (*d.*) Find the maximum height of the trajectory.
9. A 4·7-inch Q.F. gun is engaging a 12-cm. gun, which is 500 feet higher (as at Ladysmith); the range is 4500 yards. The data for the 4·7-inch Q.F. are to be got from Range Table (p. 62), and the 12-cm. gun is considered as equivalent to the 4·7-in. Q.F., and the same data hold good.
   On a diagram mark for each gun the angles of tangent and quadrant elevation, and of descent and arrival, with their values.
10. Determine the coefficient of reduction n employed in the 4·7-inch Q.F. Range Table (p. 62) at the ranges of 2400 yards and 4500 yards respectively.
11. A 4·7-inch Q.F. gun is 100 feet above sea-level. Determine the height above muzzle-level of an eminence or bluff, 500 yards to the front, which will mask the fire out to sea at ranges of 2000 and 4000 yards.
12. Prove that in firing seawards, at a range of 2000 yards with a muzzle velocity reduced to 1690 f/s, the 4·7-inch Q.F. shot will clear an obstacle 27 feet above the level of the gun and 500 yards from it; gun is 100 feet above sea-level.
13. From the Range Table of a 6-inch B.L., III, we have
    V = 1327 f/s; remaining velocity after 2000 yards is 1025 f/s; jump is nil; tangent elevation for 4000 yards is 8° 58′.
    Time of flight for 4000 yards is 11·59 seconds, and for 2000 yards 5·22 seconds, take $n = 1$.
    Calculate by the D table (Table V), the angle at which the shot is moving when it has advanced 2000 yards in a range of 4000 yards. Prove that the shot is then about 530 feet high in the air.
14. With the Lee-Metford rifle, find the striking velocity for every 200 yards up to 1000 yards. Data are
    V = 2050 f/s, $w = 215$ grains, $d = 0{\cdot}307$ inch, $n = 0{\cdot}78$.
    7000 grains = 1 lb. avoirdupois.
15. With the same rifle as in Example (14) find the time of flight over each range.
16. Find the elevation necessary for a 12-inch B.L. projectile to attain a range of 5900 yards. Given V = 2400 f/s, $w = 850$ lbs., $n = 0{\cdot}97$, jump = − 8′, and employing Table X.

17. Taking the 6-inch B.L., VII, Range Table (p. 65) and values for $\frac{R}{C} = 500, 1000, 2000, 3000$, show by means of Table X., and sin $2\phi = C.a$, that the ballistic coefficient increases as the elevation increases.

18. Draw on squared paper, to suitable scales, the curves showing

(*a.*) Elevation and range;
(*b.*) Remaining velocity and range;
(*c.*) Angle of descent and range;
(*d.*) Time of flight and range;

for 6-inch B.L., VII (see Range Table, p. 65). Suitable ranges would be 500, 750, 1000, 2000, 3000, &c., yards.

19. A 4·7-inch Q.F. is on the reverse slope of a hill and firing at a target (on same level as the gun), 4000 yards distant; the distance from gun to top of slope is 500 yards and the slope of the hill is 3°; will the shot clear the ridge? (See Range Table, p. 62.)

20. Using Orde Browne's rule, what will be the penetration into wrought-iron plate of

(*a.*) 12-inch B.L., IX, M.V. = 2616, w = 850 lbs.;
(*b.*) 9·2-inch B.L., IX., M.V. = 2740, w = 380 lbs.;
(*c.*) 6-inch B.L., VII, M.V. = 2493, w = 100;

at a range of 4000 yards.

21. Assume Ingall's empirical formula for variation in the weight of the projectile,

$$\frac{\Delta V}{V} = \pm \tfrac{7}{16} \frac{\Delta W}{W},$$

where

ΔW is the change in weight of projectile,
ΔV is the change in muzzle velocity.

What M.V. may be expected for the star shell (w = 31 lbs.) of the 5-inch Howitzer (charge is core and one ring), given that the same charge with a 50-lb. projectile produces a M.V. = 556 f/s, the driving bands of both shells being the same?

[Range Table gives M.V. = 650 f/s for the star shell.]

22. Assuming Ingall's empirical formula

$$\frac{\Delta V}{V} = \pm \tfrac{5}{8} \frac{\Delta w}{w},$$

where

Δw is the change in weight of charge,
ΔV is the change in muzzle velocity.

What M.V. may be expected when the charge is $6\frac{5}{16}$ ozs., given that a charge of $11\frac{7}{16}$ ozs. gives a M.V. of 782 f/s in a 5-inch Howitzer? The 50-lb. shot is used in both cases.

[The Range Table gives the M.V. as 556 f/s.]

23. From Example 15, page 40; show, by using the formula sin $2\phi = Ca$ that

$$\frac{\phi'}{\phi} = \frac{1}{m}$$

for flat trajectories.

SECTION 3.—COMPILATION OF RANGE TABLES.

The Range Table of a gun can only be taken as a guide; the data on which a Range Table is compiled are obtained from the results of firing at Shoeburyness on as calm a day as possible, with a comparatively new gun and with carefully prepared ammunition.

There are many causes which lead to difference between the shooting of a gun when fired, say, at annual practice and the shooting of a gun of the same nature in the practice on which the Range Table has been based.

The amount of wear in the bore of the gun, the lot of cordite used, and the temperature of the cordite charge itself may affect the muzzle velocity considerably.

The flight of the projectile itself is affected by the density and humidity of the air, by wind, and by the jump, which can only be ascertained at low angles of elevation.

The official compilation of Range Tables is carried out under the direction of the Ordnance Committee, Woolwich, special tables by Captain Ingalls are used, when convenient.

The tables employed here are those at the end of the book; these are founded on Professor Bashforth's experiments. In the present chapter direct fire only will be dealt with; Part II. of this book deals with high-angle fire.

To obtain the necessary data on which to base the compilation of a Range Table, two series of firing are required.

In the first series five or more rounds are fired at a wooden target, 9 feet square, at 500 yards, for guns of small calibre or low velocity, or at 1000 yards for larger natures. These rounds are fired through two sets of electrical screens, each set connected with Boulangé chronographs; one set is near the gun and the other is placed so that the middle point between its two screens is 500 yards, or 1000 yards from the muzzle of the gun.

By the first series of firing we get the muzzle velocity of the gun, the jump, ballistic coefficient, and coefficient of reduction for one range.

The gun is laid on the bull's-eye of the target by means of cross wires at the breech and muzzle ends of the bore, the angle of depression is recorded by means of a clinometer; sufficient elevation is then given to ensure the target being struck as near the bull's-eye as possible. The rounds are fired and the velocities of the shots at the mid point between two screens of each set of screens are recorded by chronograph; such velocities are called "observed velocities."

EXAMPLE.

Series I (a).

Gun	15-pr. Q.F.	
Projectile ...	Shrapnel shell, weight 14 lb. 6 oz.	
Velocity screens...	1st pair ...	1st screen, 70 feet from muzzle.
		180 feet between screens.
	2nd pair ...	1st screen, 470 yards from muzzle.
		180 feet between screens.
Barometer ...	30·50 inches.	
Thermometer ...	34 degrees.	

Digitized by Google

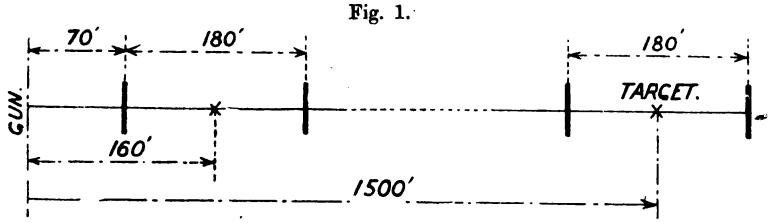
The quadrant angle of depression of the gun when laid on the target by cross wires in the bore was 24 minutes, and the gun was then elevated through an angle of 22 minutes, this being considered, from experience and an estimate of the muzzle velocity, sufficient T.E. to hit a target 500 yards off. The results of firing (omitting Round 1) were :—

No. of Round.	Observed velocity at 160 ft. from muzzle.	Observed velocity at 500 yds. from muzzle.	Shot struck with regard to centre of target.
	f.s.	f.s.	inches.
2	1585	1415	2·5 up
3	1590	1415	3·5 „
4	1570	1398	5·0 down
5	1598	1424	Centre
6	1594	1422	7·2 down
	Mean point of impact		1·24 down

As the mean point of impact is only 1·4 inches below the centre of the target, the *tangent elevation* for 500 yards may be taken as 22′ (mean).

We now take each round separately, and determine in the following order C, the M.V. and the jump. For round 2 we have :—

Fig. 1.



$$C = \frac{1500 - 160}{S_{1585} - S_{1415}} = \frac{1340}{775{\cdot}8} = 1{\cdot}728.$$

We get the muzzle velocity, V, from

$$S_V = S_{1585} + \frac{160}{1{\cdot}728},$$

$$= 43541{\cdot}1 + 92{\cdot}6,$$

$$= 43633{\cdot}7,$$

$$\therefore V = 1606 \text{ f/s.}$$

To find the Jump.—In fig. 2 we see the direction of the axis of the piece when ready to be fired; on firing the gun and before the shot has left the bore, this direction is changed by an angle, J, called the angle of jump, and at present unknown.

Suppose the direction of the shot on leaving the muzzle to be the line of departure, as shown, then we know that T.E. = 22′ in this case, and if ϕ, the angle of projection, be found, we see that

$$\text{angle } \phi - \text{angle of T.E.} = \text{angle J} = \text{jump.}$$

By this method the jump is found.

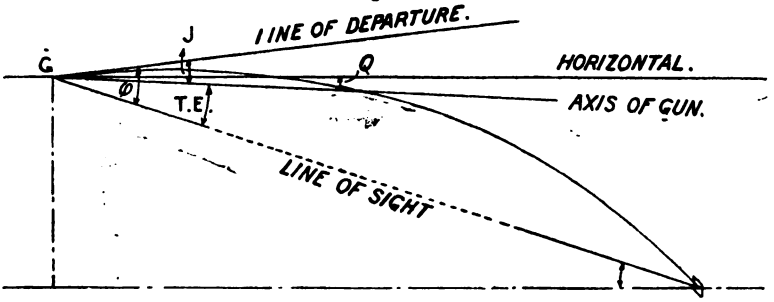
Digitized by Google

ϕ is got from the formula

$$\sin 2\phi = Ca$$

and Table X.

Fig. 2.



The M.V. is 1606 f/s, but, to simplify the work and with inappreciable error, we will take V = 1610 f/s.

With V = 1610 and $\frac{R}{C} = \frac{500}{1{\cdot}728} = 289{\cdot}4$, from Table X,

$$a_{300} = 0{\cdot}01220$$
$$a_{200} = 0{\cdot}00785$$
$$\text{Diff.} = 0{\cdot}00435.$$
$$\therefore\ a_{289{\cdot}4} = 0{\cdot}00785 + \frac{89{\cdot}4}{100} \times 0{\cdot}00435$$
$$= 0{\cdot}00785 + 0{\cdot}00388$$
$$= 0{\cdot}01173.$$
$$\therefore\ \sin 2\phi = C.a$$
$$= 1{\cdot}728 \times 0{\cdot}01173$$
$$= 0{\cdot}0203,$$
$$2\phi = 1^\circ\ 10'$$
$$\phi = 35',$$
$$\text{Jump} = \phi - T = 35' - 22' = 13'.$$

Repeating the above method in each of the other rounds, we get

No. of round.	C.	Muzzle velocity.	Jump.
2	1·728	1606	+ 13 minutes.
3	1·680	1612	+ 13 „
4	1·691	1591	+ 13·75 „
5	1·697	1620	+ 12·50 „
6	1·714	1616	+ 12·50 „
Means . . .	1·702	1609	+ 12·95 minutes.

In finding the jump for each round, the nearest velocity divisible by ten was taken, thus for 1612 f/s, 1610 was chosen; for 1616, 1620 was chosen.

The jump may be taken as 13′ (positive).

Digitized by Google

To find the coefficient of reduction, n; then to find $\kappa\sigma$

$$C = \frac{w}{nd^2} = \frac{w}{\kappa\sigma \cdot \tau \cdot d^2} = 1{\cdot}7,$$

and τ from Table XI $= 1{\cdot}072$,

$$w = 14{\cdot}375,$$
$$d = 3,$$
$$\text{and } \kappa\sigma = \frac{14{\cdot}375}{1{\cdot}072 \times 9 \times 1{\cdot}7} = \frac{w}{\tau \times d^2 \times C}.$$

$$\log C = 0{\cdot}2304$$
$$\log \tau = 0{\cdot}0302$$
$$\log d^2 = 0{\cdot}9542$$
$$\log C\tau d^2 = \overline{1{\cdot}2148}$$
$$\log w = 1{\cdot}1577$$
$$\therefore \log \kappa\sigma = \overline{1{\cdot}9429}$$
$$\kappa\sigma = 0{\cdot}8768$$

From Series I (a) we have therefore

$$V = 1609,$$
$$C = 1{\cdot}7,$$
$$\text{Jump} = 13 \text{ minutes (positive)},$$
$$\kappa\sigma = 0{\cdot}8768,$$
$$\tau = 1{\cdot}072.$$

For the next series we have :—

RESULTS OF PRACTICE IN SERIES I (b).

Barometer—30·50 inches.
Thermometer—dry bulb, 34 degrees; wet bulb, 29 degrees.

Abstract.

Rounds.	Elevation (quadrant).	Means.					Height of axis of gun above sands.	Wind.	
		Time of flight.	Range.	Error in range.	Lateral deviation.	Error in direction.		Velocity (70 feet above ground).	Force and direction.
	° ′	secs.	yards.	yards.	yards. R.	yards.	feet.	f/s.	
5	2 0	4·00	1661	13·2	4·1	1·36	15·3	16	
6	5 0	7·98	2955	13·5	14·8	1·7	16·9	17	
6	8 0	11·77	4040	21·8	28·0	2·06	18·3	14	2 to 4
6	12 0	16·45	5194	10·2	56·2	5·37	19·5	13	
6	16 15	5 rnds. 21·13	6210	16·8	103·0	5·3	21·13	16	

Digitized by Google

First of all the tangent elevations will be found.

In the 2° series, we see that the gun is 15·3 feet above the target, which is 1661 yards off, hence the angle of sight (S minutes) due to this must be added to the quadrant elevation of 2′ to get the tangent elevation.

$$S = \tan^{-1} \frac{15{\cdot}3}{1661 \times 3} = \tan^{-1} 0{\cdot}00307 = 10\tfrac{1}{2} \text{ minutes},$$

or thus

$$S' = 1146 \frac{15{\cdot}3}{1661} \text{ (see p. 5)}$$

$$= 10\tfrac{1}{2}, \text{ by slide rule.}$$

Proceeding in a similar manner for each elevation, we get

	° ′	° ′	° ′	° ′	° ′
Quadrant elevations ..	2 0	5 0	8 0	12 0	16 15
Angle of sight	0 10½	0 6½	0 5	0 4	0 4
	° ′	° ′	° ′	° ′	° ′
Tangent elevations ..	2 10½	5 6½	8 5	12 4	16 19
Jump (+)..	0 13	0 13	0 13	0 13	0 13
	° ′	° ′	° ′	° ′	° ′
Angles of projection, ϕ ..	2 23	5 19	8 18	12 17	16 32

Next to determine the correct coefficient of reduction at each elevation.

In the 2° series, the correction for height of trajectory may be neglected; the atmospheric conditions in Series I (a) and I (b) being the same, we may take C as found before,

$$C = 1{\cdot}7,$$

$$\tau = 1{\cdot}072,$$

$$\kappa\sigma = 0{\cdot}8768.$$

To test how far this is correct, we employ the direct fire formula

$$\sin 2\phi = Ca$$

$$\log \sin 2\phi = \log \sin 4° 46′ = \bar{2}{\cdot}9196$$

$$\log C = 0{\cdot}2304$$

$$\log a = \bar{2}{\cdot}6892$$

$$a = 0{\cdot}04889.$$

Looking out in Table X against this value of a for V = 1610 f/s (instead of 1609), we see that

$$a_{1000} = 0{\cdot}05050$$

$$a_{900} = 0{\cdot}04417$$

$$\text{Difference} = 0{\cdot}00633.$$

Digitized by Google

Let $x\left(=\frac{R}{C}\right)$ be the required "reduced range," then

$$a_x = 0{\cdot}04889$$
$$a_{900} = 0{\cdot}04417$$
$$\text{Difference} = 0{\cdot}00472$$
$$\therefore x = 900 + \frac{0{\cdot}00472}{0{\cdot}00633}\,100 = 900 + 74{\cdot}56,$$

so that

$$\frac{R}{C} = 974{\cdot}56,$$
$$R = 974{\cdot}56 \times 1{\cdot}7 = 1657 \text{ yards.}$$

This is only 4 yards less than that found in practice, therefore we may take at a range of 1660 yards

$$C = 1{\cdot}7,$$
$$\kappa\sigma = 0{\cdot}8768.$$

Next take the series where

$$\phi = 5^\circ\ 19';$$

the mean height of the trajectory must be found; the maximum height is

$$4T^2 = 4 \times (7{\cdot}98)^2 = (15{\cdot}96)^2 = 255 \text{ feet.}$$

The average or mean height of the shot for the tenuity correction is $\frac{2}{3}$ of the maximum.

$$\tfrac{2}{3} \text{ of } 255 = 170 \text{ feet.}$$

This is very small and may be neglected, so that for the 5° series we take

$$C,\ \tau,\ \kappa\sigma \text{ as for the } 2^\circ \text{ series.}$$

This value of C can be tested by the same process as was shown for the 2° series.

For the 8° series,

$$\text{Mean height of trajectory} = \tfrac{2}{3} \cdot 4\,(11{\cdot}77)^2 = 368 \text{ feet.}$$

At the normal barometric height of 30 inches, the rate of fall is 1 inch per 1000 feet, or a reduction of 3·3 % in the density of the air at 1000 feet height.

For 368 feet the reduction will be $\frac{3{\cdot}3}{3}$ or 1 % (nearly), so that we take the correction for the tenuity factor to be

$$0{\cdot}99.$$
$$\therefore C = \frac{1{\cdot}7}{0{\cdot}99} = 1{\cdot}72 \text{ about.}$$

Working with this, we find from $\phi = 8^\circ\ 18'$, V = 1610 and the formula $\sin 2\phi = Ca$, that the range is too small.

Trying C = 1·75, we find

$$\sin 16^\circ\ 36' = 1{\cdot}75 \times a,$$
$$a = 0{\cdot}1632,$$

with a M.V. = 1610, this gives us $\frac{R}{C} = 2291$,

$$\text{or Range (R)} = 4010 \text{ yards.}$$

Digitized by Google

This is sufficiently close to 4040 yards, the actual range as measured.

So that at 4000 yards we may take C = 1·75.

For the 12° series, we find by trial that C = 1·78 is about right; C = 1·77 gives a calculated range of 5111 yards, whereas the measured range is 5194.

The 16° series will be considered later.

It will be found very useful to tabulate the *tangent* elevations for every 100 yards at this stage, as it enables us to determine the approximate angle of descent in the following calculations, and thereby save labour. Taking the ranges as abscissæ and the tangent elevations on page 50 as ordinates, we plot a curve, bearing in mind that the origin will not be at zero, but a point corresponding to 13 minutes *below* the zero point, on account of the jump being positive (had the jump been negative, the origin would be at 13 minutes *above* the zero point); it is also to be remembered that we have a very important point on the curve at the 500 yards range, where the ordinate is 22 minutes, as found in the calculations on Series I (*a*).

We have thus seven points on the curve, including the origin (which is given us by the jump), and if the practice has been good and the data is reliable no point should be off the curve when a flexible ruler is applied to them, in fact, in a good example like the present one, the prolongation of the curve below the 500 yards point may almost be relied upon to find the jump without any calculation; in this case it confirms the calculations.

It will generally be found desirable, especially with high-velocity guns, and in cases where the interval between the target and the next range is great, to calculate an intermediate point on the curve, for any slight sagging of the flexible ruler at this point when striking the curve may easily make a couple of minutes error in the elevation, which here means an appreciable error in the range.

Thus to interpolate some tangent elevations for ranges between 300 and 1700 yards.

Our muzzle velocity is 1609; this we may take as 1610 f/s.

Then with V = 1610, C = 1·7 :—

$\frac{R}{C}$	200	295	400	600	1000
R	340	500	680	1020	1700
a	0·00785	0·01198	0·01682	0·02692	0·05050
$\sin 2\phi = a.C$	0·01326	0·02036	0·02859	0·04576	0·08584
2ϕ	46′	1° 10′	1° 38′	2° 37′	4° 55′
ϕ	23′	35′	49′	1° 18′	2° 27′
Jump	13′	13′	13′	13′	13′
T.E. $= \phi - J$	10′	22′	36′	1° 5′	2° 14′

Digitized by Google

(a.) Tangent Elevation.

The curve giving the tangent elevation for any range being thus plotted, the Range Table column giving the T.E. for every 100 yards or 50 yards, can be filled in from the curve.

In this case and in all the following it will generally be found, on comparing the "differences" for each elevation, that there are little irregularities due to the impossibility of reading to very small increments on the squared paper. It is necessary, therefore, to "smooth" the curve; that is, to jot down in pencil, between each two elevations, the difference between them, and then correct these differences so as to make them all increase regularly. Care must be taken, of course, that if any "difference" is increased there must be an equal decrease made in a neighbouring one, so as not to alter the mean run of the curve.

(b.) Remaining Velocity.

These are the actual, that is, the striking velocities, which are calculated below (see page 55), and which are given in a table. Here we take the *calculated* range as the abscissa, and the corresponding remaining velocity as the ordinate; the latter for range *nil* will, of course, be the muzzle velocity. The calculations will never give such exact results that all the points will come absolutely on a curve, and it will be necessary to alter points here and there until they do. In the case under consideration all seven points come on a curve if 900 be altered to 906, or it may be preferred to make a smaller alteration at this point and increase each of the three subsequent velocities by 2, 3, and 5 f/s respectively; the former alternative is preferred, however.

Having determined the curve, take off the velocity for every 100 yards, and insert in the Range Table.

(c.) Alteration in Range due to 5′ alteration in Elevation.

The method of preparing this column is obvious; the alteration in range is calculated for various points—say, every 500 yards—and the intermediate ones interpolated by means of a curve.

(d.) 5′ in Elevation or Deflection alters the Point of Impact vertically or laterally.

The correction, in either case, is

$$R \times \tan 5'.$$

Calculate this for every 500 yards or so (a slide rule is very useful for the purpose), plot the results on a curve for each of the ranges dealt with, and read off the results for all intermediate points.

The correction R tan 5′ for height may be seen at once from fig. 4; it is there seen that 5′ extra elevation makes a vertical difference at the target of TM, and from the triangle TMF,

$$TM = TF' \tan 5' = R \tan 5'.$$

The correction R tan 5′ for deflection may be shown thus:—

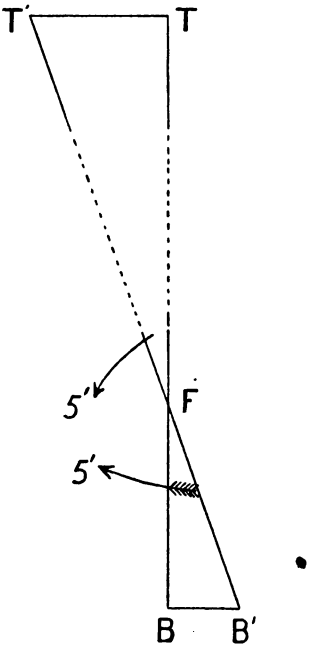
Let B be the backsight, F the foresight of a gun, T the target,

Digitized by Google

then if a deflection BB′ be given such that BFB′ is an angle of 5′, we see that the alteration of the point of impact is TT′ and

$$TT' = TF \tan 5' = R \tan 5' \text{ (see fig. 3).}$$

Fig. 3.



(e.) Angle of Descent (β).

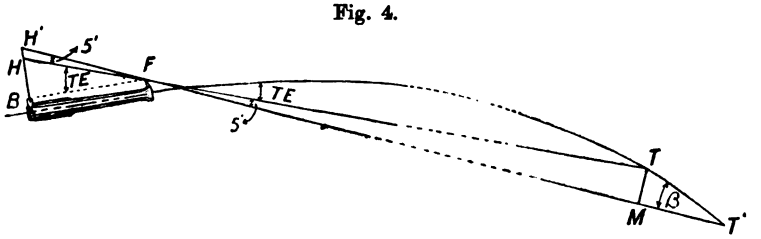
In fig. 4 we see that if 5 minutes extra elevation is given, we get a range increased by MT′.

Taking TT′ as a straight line, we have

$$\begin{aligned} \Delta R = MT' &= TM \cot \beta, \\ &= TF \tan 5' \cot \beta, \\ &= R \tan 5' \cot \beta. \end{aligned}$$

The 5′ extra elevation column (already obtained) gives us the actual value of MT′ at any range, hence since ΔR, R, tan 5′ are known, we get cot β and thence β.

Fig. 4.



This method gives a very approximate and ready means of finding the angle of descent, and it is a useful check in the work of calculating the angles of descent.

Subjoined is a table showing the calculation of remaining velocities,

Digitized by Google

M.V. = 1609 f/s; C = 1·7; v_0 is the velocity at the vertex.

Range in yards.	$\frac{s}{C}$.	$S_V - \frac{s}{C} = S_v$.	v.	T_v.	$T_V - T_v = \frac{t}{C}$.	t.	$\frac{1}{2}\frac{t}{C}$.	$T_V - \frac{1}{2}\frac{t}{C} = T_v$.	v_0.	D_{v_0}	D_v.	$D_{v_0} - D_v = \frac{\beta}{C}$.	β.

times of flight, and angles of descent. Beyond 3000 yards a new value of C must be taken according to what has already been found. In each case a curve is drawn by plotting, as described for tangent elevations, the ordinates representing times of flight, remaining velocities, angles of descent, as the case may be, the abscissæ representing range in yards. If any point is much off the curve, the calculation for that range must be scrutinised, and an error may be detected up to 2000 yards, C = 1·7.

(*f.*) *To Strike an Object* 10 *feet high, the Range must be known within* $\frac{5}{8}$ cot β *yards.*

The figures in this column are merely the values $(\frac{1}{2} \cdot \frac{10}{8})$ cot β or $\frac{5}{8}$ cot β yards, where β is the angle of descent at each range.

(*g.*) *Fuze Scale.*

This is obtained from the results of firing: as an example:—

Setting of Fuzes.	Mean Time of Burning.	
	As observed. (Barometer 30·50 inches.)	Corrected for Barometer. 30·00 inches.
	seconds	seconds
5	4·37	4·42
9	8·35	8·45
14	14·66	18·84
18	19·57	19·81

The rule for obtaining the corrected time of burning is that 1 inch of diminution in height of barometer increases the time of burning by 0·03 of the total time for any particular setting, and *vice versâ* for an increase in height of barometer.

Column (3) above is therefore obtained from column (2) by multiplying the figures in the latter by 1·015 to obtain the correction for $\frac{1}{2}$ inch.

The procedure is now as follows:—

Plot a curve of settings and times from the data in columns (1) and (3) in the above table; consult the time and range curve [already plotted from the actual practice], and note the times for every 100 yards from this curve; then, from the time and settings curve, the setting for every 100 yards in range can be read off (in units, halves, and quarters).

(*h.*) *Probability Columns* (*see Chapter III, Section* 2).

Taking the length column first, multiply the mean error in range in each series by 1·69, and the result is the length of the probable rectangle for that series; these are all plotted as ordinates, with the range corresponding as the abscissa. The starting-point of the curve will not be at zero, but at the 500 yards target; in this we have only the mean vertical error, which is 3·9 inches, and as the angle of descent at 500 yards was found by calculation to be 37 minutes, the mean error in range is—

$$\frac{3{\cdot}9 \times \cot 37'}{36} = 10 \text{ yards.}$$

This, multiplied by 1·69, gives the first point for the curve.

Digitized by Google

The mean error at the next point, was [see Series I (*b*)] 13·2 yards at 1,661 yards range, and so on at other ranges; a curve is plotted out for the 50% length zones and a similar procedure is followed for the breadth and height zones.

An example in high-angle fire is here worked out, but the explanation belongs to Part II.

In Series I (*b*)

$$\phi = 16° 32',$$

and it is required to find the range.

Approximately the maximum height of the trajectory is

$$4\,(T^2) = 4\,(21{\cdot}13)^2 = 1786 \text{ feet.}$$

Two-thirds of this is 1190 or roughly 1200 feet.

At this height the density of the air is less than at the surface of the earth.

We know that there is a fall of 1 inch for 1000 feet, so that for 1200 feet there is a fall of 1·2 inches; the normal barometric height being 30 inches, this implies a reduction of 3·3 % in the density of the air for a rise of 1000 feet and for 1200 feet rise, a reduction of $3{\cdot}3 \times 1{\cdot}2 = 4\ \%$, so that, if the value of C was 1·7 at the 2° elevation, its value now will be

$$\frac{1{\cdot}7}{1 - 0{\cdot}04} = \frac{1{\cdot}7}{0{\cdot}96} = 1{\cdot}77.$$

Try

$$C = 1{\cdot}77.$$

We now take the arc of the trajectory up to the highest point.

$$\tan\phi - \tan\theta = C \sec\eta\,(I_U - I_u),$$

and, of course, θ being equal to zero at vertex,

$$\tan\phi = C \sec\eta\,(I_U - I_{u_0}),$$

$$\therefore\ I_{u_0} = I_U - \frac{\tan\phi}{C \sec\eta}.$$

We know that

$$V = 1609, \quad T = 21{\cdot}13, \quad \phi = 16° 32',$$

$$\eta = \frac{\phi}{2} = 8° 16'.$$

$$\therefore\ U = V \cos\phi \sec\eta$$
$$= 1559 \text{ f/s.}$$

$$\log V = 3{\cdot}2065560$$
$$\log \cos\phi = \bar{1}{\cdot}9816620$$
$$\log \sec\eta = 0{\cdot}0045361$$
$$\log U = 3{\cdot}1927541$$

$$\therefore\ I_{u_0} = I_{1559} - \frac{\tan 16° 32'}{1{\cdot}77 \sec 8° 16'} = I_{1559} - F, \text{ say,}$$

$$= 0{\cdot}866349 - 0{\cdot}1660$$
$$= 0{\cdot}700349$$
$$u_0 = 855 \text{ f/s.}$$

$$\log 1{\cdot}77 = 0{\cdot}2479733$$
$$\log \sec 8° 16' = 0{\cdot}0045361$$
$$0{\cdot}2525094$$
$$\log \tan 16° 32' = \bar{1}{\cdot}4725318$$
$$\log F = \bar{1}{\cdot}2200224$$

Digitized by Google

Now, using the formula

$$\frac{y_0}{x_0} = \tan\phi - C \sec\eta \left\{ I_U - \frac{A_U - A_{u_0}}{S_U - S_{u_0}} \right\},$$

$$A_{1559} = 8314{\cdot}08 \qquad S_{1559} = 43426{\cdot}5$$
$$A_{855} = 3649{\cdot}83 \qquad S_{855} = 37581{\cdot}8$$
$$\text{Difference} = 4664{\cdot}25 \qquad \text{Difference} = 5844{\cdot}7$$

$$\therefore \frac{A_U - A_{u_0}}{S_U - S_{u_0}} = 0{\cdot}7982.$$
$$I_{1559} = 0{\cdot}866349.$$

$$\therefore \frac{y_0}{x_0} = \tan 16^\circ 32' - 1{\cdot}77 \sec 8^\circ 16' \times 0{\cdot}068149$$
$$= 0{\cdot}2968464 - 0{\cdot}1220$$
$$= 0{\cdot}17485.$$

Having found $\frac{y_0}{x_0} = 0{\cdot}17485$, the next step is to find x_0.

$$x_0 = C \sec\eta \{S_U - S_{u_0}\}$$
$$= 10{,}470 \text{ feet (nearly)}.$$

$$\therefore y_0 = 10{,}470 \times 0{\cdot}17485$$
$$= 1829 \text{ feet}.$$

$$\log 10{,}470 = 4{\cdot}0197$$
$$\log 0{\cdot}17485 = \bar{1}{\cdot}2426$$
$$3{\cdot}2623$$

At the vertex the actual velocity is

$$v_0 = u_0 \cos\eta \sec\theta = u_0 \cos\eta$$
$$= 846 \text{ f/s (nearly)}.$$

To find the time to reach the highest point,

$$T_{1559} = 232{\cdot}4854$$
$$T_{855} = 227{\cdot}0629$$
$$\frac{t_0}{C} = 5{\cdot}4225$$
$$t_0 = 9{\cdot}6 \text{ seconds}.$$

Plotting the tangent elevations and ranges already found, it is found that the difference in elevation for the two ranges of 6000 and 6200 yards is about 50 minutes.

We therefore get an approximate angle of descent from

$$\tan\beta = \frac{6110 \tan 50'}{200}.$$

$$\log 6110 = 3{\cdot}7860$$
$$\log \tan 50' = \bar{2}{\cdot}1627$$
$$\text{by addition} = 1{\cdot}9487$$
$$\log 200 = 2{\cdot}3010$$
$$\therefore \log \tan\beta = \bar{1}{\cdot}6477$$
$$\beta = 24^\circ \text{ about}.$$

Digitized by Google

Try $\beta = 26°$ as the angle of descent at a range of 6100 yards, and take an arc for the descent over 0° to − 25°, so as to locate the shot when descending at an angle of 26°.

$$\phi = 0, \quad \theta = -\beta = -26°.$$

Our value η' will be − 13°; dropping the suffix we have our new $\eta = -13°$.

$U_0 = v_0 \sec \eta = 846 \sec 13°.$

$$\log 846 = 2{\cdot}9274$$
$$\log \sec 13° = 0{\cdot}0113$$
$$\log U_0 = 2{\cdot}9387$$

$U_0 = 868$ f/s.

We now use the formula

$$\tan \beta = C \sec \eta \, (I_{U_0} - I_u),$$

where u is the velocity at the point of impact, so that

$$I_u = I_{u_0} - \frac{\tan \beta}{C \sec \eta}.$$

$$\log C = 0{\cdot}2480$$
$$\log \sec 13° = 0{\cdot}0113$$
$$\text{by addition} = 0{\cdot}2593$$
$$\log \tan 26° = \bar{1}{\cdot}6882$$
$$\therefore \log \frac{\tan \beta}{C \sec \eta} = \bar{1}{\cdot}4289.$$
$$\therefore I_{u_0} = I_{868} = 0{\cdot}7106.$$
$$\therefore I_u = 0{\cdot}7106 - 0{\cdot}2685 = 0{\cdot}4421.$$
$$u = 653 \text{ f/s}.$$

To find the horizontal distance traversed in the descending branch, or

$${}_0x_{26} = C \, (S_{U_0} - S_u).$$

$$S_{U_0} = S_{868} = 37815{\cdot}4$$
$$S_u = S_{653} = 33114{\cdot}2$$
$$\text{Difference} = 4701{\cdot}2$$

$${}_0x_{26} = 1{\cdot}77 \times 4701{\cdot}2$$
$$= 8322 \text{ feet}.$$

$$\log 1{\cdot}77 = 0{\cdot}2480$$
$$\log 4701{\cdot}2 = 3{\cdot}6722$$
$$3{\cdot}9202$$

For the descending branch we have

$$\frac{y'_0}{x'_0} = C \sec \eta' \left[I_{U_0} - \frac{A_{U_0} - A_u}{S_{U_0} - S_u} \right].$$

$$A_{U_0} = A_{868} = 3814{\cdot}61$$
$$A_u = A_{653} = 1053{\cdot}89$$
$$2760{\cdot}72$$

$$S_{U_0} - S_u = 4701{\cdot}2.$$

Digitized by Google

$$\therefore \frac{y'_0}{x'_0} = 1{\cdot}77 \sec 13^\circ \left[0{\cdot}7106 - \frac{2760{\cdot}7}{4701{\cdot}2}\right]$$

$$= 1{\cdot}77 \sec 13^\circ \times 0{\cdot}1229$$

$$= 1858 \text{ feet.}$$

This is very near to the height previously found, namely, 1829 feet, so that an angle of descent of 26° is correct.

We have therefore established the following results:

$$\phi = 16^\circ\ 32'$$

$$\text{Range} = 10{,}470 + 8322 = 18{,}792 \text{ feet}$$

$$= 6264 \text{ yards}$$

[the measured range being 6210 yards].

Angle of descent 26°.

The time for the descending branch can be found in the same way as was done for the ascending branch; the two added together should be near to the time actually measured, namely, 21·13 seconds.

Examples.

From the following report work out the value of the ballistic coefficient, the muzzle velocity, the jump and the coefficient of reduction.

Report of experimental practice with 5-inch, 60-pr. B.L. gun.

Projectile: shrapnel shell, weighted and with plug, 60 lbs.

Charge: $9\frac{7}{16}$ lb. cordite, M.D. size 16, primed 12 drams, R.F.G.$_2$ at each end. Temperature 67°.

Barometer: 30·28 inches.

Thermometer: 66°.

Quadrant elevation to gun.	Quadrant depression to point struck.	Observed velocity at 145 feet.	Observed velocity at 3000 feet.

RANGE TABLE FOR 6-INCH B.L. GUN, MARK VII (FOR LAND SERVICE).

Based on Practice of 7.5.00, previous to which the gun had fired 8 proof and 7 full charges.

Minutes 49,349 III, 49,350, 52,791 II. $\frac{40185}{9758}$

Charges, { weight, 20 lb., cordite, size 20. gravimetric density, $\frac{85\cdot75}{0\cdot324}$. weight, 23 lb., cordite M.D., size 16. gravimetric density, $\frac{74\cdot5}{0\cdot372}$.

Projectile, { nature, cast steel common shell, Mark I, pointed. weight, 100 lb.

Muzzle velocity, 2,493 f.s., at 60° Fahr.

Nature of mounting, pedestal.

Jump, +3 minutes.

Remaining velocity (actual).	To strike an object 10 feet high, range must be known within	Angle of descent.	5 minutes elevation or deflection alters point of impact.		Elevation.	Range.	Fuze scale for fuze, time and percussion, middle, No. 54, Marks I*, II and III.	50 per cent. of rounds should fall in			Time of flight.	Penetration into wrought iron.

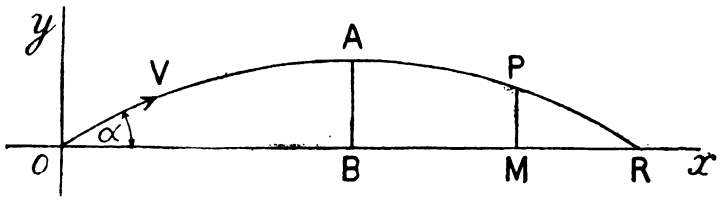
SECTION 4.—UNRESISTED MOTION OF A PROJECTILE.

Although the preceding problems and illustrations of artillery fire have shown that the force of gravity is usually a comparatively small effect in comparison with the resistance of the air, insomuch that it may be neglected in a calculation to a first approximation of the trajectory, occasions may still arise where it is the resistance of the air which is the negligible quantity, as in the case of high-angle howitzer fire, with heavy projectiles, and small charges and low initial velocities.

For this reason it is advisable to add a short account of the theory of the motion of an unresisted projectile in accordance with the principles discovered by Galileo in 1638.

Fig. 1.



The shot is supposed to be projected with velocity V f/s at an elevation α, and to have advanced a horizontal distance OM $= x$ feet and to have ascended a vertical height MP $= y$ feet, in t seconds from leaving the muzzle (fig. 1).

Then
$$\text{OM} = x = \text{V}t\cos\alpha$$
$$\text{MP} = y = \text{V}t\sin\alpha - \tfrac{1}{2}gt^2;$$

in accordance with the laws of motion; the horizontal velocity V cos α of the shot remaining unaltered during the flight, while the vertical velocity diminishes from

$$\text{V}\sin\alpha \text{ to } \text{V}\sin\alpha - gt, \text{ in } t \text{ seconds.}$$

If T denotes the time of flight down to the ground again, taking the ground as horizontal, and if the range over the ground is X feet, then, putting $y = 0$, we find

$$\text{T} = \frac{2\text{V}\sin\alpha}{g},$$

and
$$\text{X} = \text{VT}\cos\alpha = \frac{\text{V}^2\sin 2\alpha}{g},$$

so that
$$\sin 2\alpha = \frac{g\text{X}}{\text{V}^2},$$
$$\text{V} = \sqrt{(\text{X}g\operatorname{cosec} 2\alpha)},$$

giving the requisite elevation α to attain a range of X feet, with an initial velocity V f/s, or the velocity V required to attain a range X with elevation α; and then

$$\text{T} = \sqrt{\frac{2\text{X}\tan\alpha}{g}}.$$

Digitized by Google

Also

$$V \sin \alpha = \tfrac{1}{2} g T,$$

so that

$$y = \tfrac{1}{2} g T t - g \tfrac{1}{2} t^2$$
$$= \tfrac{1}{2} g t (T - t) = \tfrac{1}{2} g t t',$$

if $t' = T - t$;

so that with $g = 32$,

$$y = 16 t t',$$

Colonel Sladen's formula employed in the preceding examples for plotting ordinates of a trajectory.

At the highest point of the trajectory, where $y = H$, suppose,

$$t = t' = \tfrac{1}{2} T,$$

so that $$H = \tfrac{1}{8} g T^2 = 4T^2 = (2T)^2;$$

hence the practical rule, "the square of twice the time of flight in seconds is the greatest height ascended in feet."

Since $$T = \sqrt{\frac{2 X \tan \alpha}{g}},$$

$$\therefore H = 4T^2 = 4 . \frac{2 X \tan \alpha}{g}$$
$$= \frac{X}{4} \tan \alpha . \text{ [taking } g = 32].$$

We have therefore, for a given range of X feet,

$$V = \sqrt{X g \operatorname{cosec} 2\alpha}$$
$$H = \frac{X}{4} \tan \alpha$$
$$T = \sqrt{\frac{2X \tan \alpha}{g}}.$$

These three formulæ will be made use of for finding the limits within which the real trajectory in a resisting medium must lie.

For instance, in the Jubilee rounds, fired in 1888, a time of flight of nearly 70 seconds was observed in a range of 12 miles; the rule would make the height ascended about 19,600 feet—more than the height of Mont Blanc.

Since $$t = \frac{x}{V \cos \alpha},$$

therefore $$y = x \tan \alpha - \frac{g x^2}{2V^2 \cos^2 \alpha},$$

the invariable relation connecting the co-ordinates x and y of a shot moving in the trajectory; and the form of this equation shows that the curve is a *parabola*, in accordance with the principles of co-ordinate geometry.

Putting $y = 0$ gives the range

$$X = \frac{2V^2 \sin \alpha \cos \alpha}{g},$$

Digitized by Google

as before; while putting $x = \frac{1}{2}X$ gives the greatest height,

$$H = \tfrac{1}{4}X \tan \alpha.$$

The equation

$$y = x \tan \alpha - \frac{gx^2}{2V^2 \cos^2 \alpha}$$

reduces to

$$\left(x - \frac{V^2}{g} \sin \alpha \cos \alpha\right)^2 = -\frac{2V^2}{g} \cos^2 \alpha \left(y - \frac{V^2 \sin^2 \alpha}{2g}\right),$$

which is of the form

$$(x - h)^2 = -2l(y - K).$$

The equation of a parabola, whose axis is vertical, and vertex at the highest point (h, K), where

$$h = \frac{V^2}{2g} \sin 2\alpha, \qquad K = \frac{V^2}{2g} \sin^2 \alpha.$$

When referred to the highest point as origin, the equation becomes

$$x^2 = 2ly,$$

so that the Latus Rectum is $2l = \dfrac{2V^2}{g} \cos^2 \alpha$.

The use of the parabolic theory will now be shown for assigning limits within which the real trajectory in a resisting medium must lie.

If V, v denote the initial and final velocities, and α, β denote the angles of projection and of descent in a real trajectory over a range of X feet, then this trajectory lies between two parabolic trajectories, having angles of departure α and β.

The range being X feet, one parabola has an angle of projection α, let the initial velocity be U_1 for the parabolic theory; similarly for the other parabola, the range is X feet, the angle of projection is β, let the initial velocity be U_2; then, taking α as less than β,

$$U_1 = \sqrt{Xg \operatorname{cosec} 2\alpha} \qquad U_2 = \sqrt{Xg \operatorname{cosec} 2\beta},$$

$$H_1 = \frac{X}{4} \tan \alpha \qquad H_2 = \frac{X}{4} \tan \beta,$$

$$T_1 = \sqrt{\frac{2X \tan \alpha}{g}} \qquad T_2 = \sqrt{\frac{2X \tan \beta}{g}}.$$

The height of the trajectory H lies between the heights of the parabolas, and therefore

$$\tfrac{1}{4}X \tan \beta > H > \tfrac{1}{4}R \tan \alpha.$$

The time of flight, T, lies between the parabolic times of flight, and therefore

$$\sqrt{\frac{2X \tan \beta}{g}} > T > \sqrt{\frac{2X \tan \alpha}{g}},$$

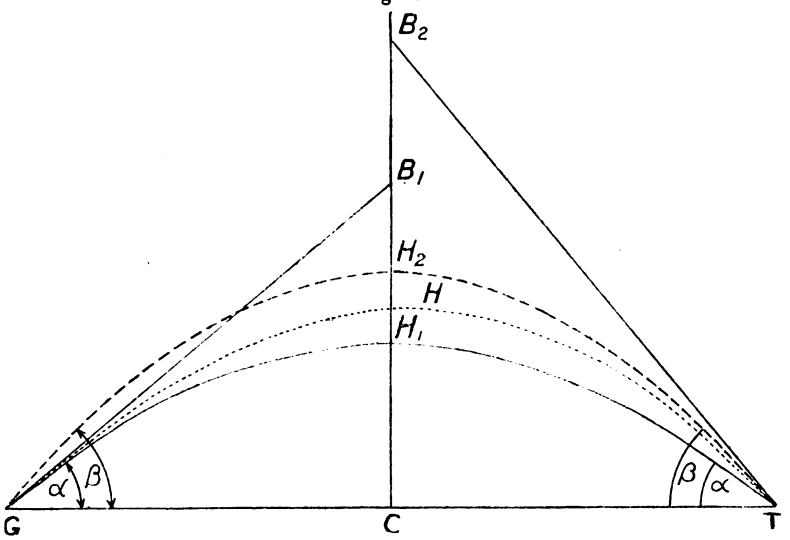
Also $\quad V > \sqrt{(Xg \operatorname{cosec} 2\alpha)}, \; v < \sqrt{(Xg \operatorname{cosec} 2\beta)}.$

Digitized by Google

Thus, in fig. 2, let GT represent the range X feet; let C be the mid point of GT and draw through C a line perpendicular to GT.

Make the angle $TGB_1 = \alpha = 40°$, then the vertex of the parabola GH_1T is at H_1, which is the mid point of B_1C (property of a parabola), and GB_1 is the tangent at G; and if $TGB_2 = 54° = \beta$, then H_2, the mid point of B_2C, is the vertex of the parabola GH_2T, and GB_2 is the tangent at G. The real trajectory, which is the curve GHT, is such that it lies altogether between the two parabolas, the trajectory

Fig. 2.



at the beginning coalesces with the lower parabola, then rises above it and at the end coalesces with the higher parabola. The highest point, H, of the real trajectory is at half time and lies between H_1 and H_2, but a little to the right of the line H_1H_2, because it lies a little beyond the half distance of the trajectory.

Thus in the trajectory of the projectile weighing 380 lbs., fired at 40° elevation from the 9·2-inch wire gun, with velocity 2375 f/s. Lieutenant Wolley Dod, R.A., found by calculation ("Proc. R.A. Institution," vol. xvi) a range of 20,765 yards, a height of vertex 17,110 feet; an angle of descent 53° 50′; time of flight 63·8 seconds; and final velocity 1090 f/s.

Here X = 62,295 feet, H = 17,110:

$$\alpha = 40°, \beta = 53° 50', T = 63{\cdot}8 \text{ seconds.}$$

Working with these data,

$$\tfrac{1}{4}X \tan \alpha = 13{,}068, \tfrac{1}{4}X \tan \beta = 21{,}305,$$

the mean being 17,180 feet;

$$\sqrt{\frac{2X \tan \alpha}{g}} = 57, \qquad \sqrt{\frac{2X \tan \beta}{g}} = 73,$$

the mean being 65 seconds, thus exhibiting on the largest scale the limits of the approximation.

As numerical exercises on the parabolic theory, the range tables of howitzers for low initial velocities may be calculated to a first approximation.

CHAPTER III.—ACCURACY.

SECTION I.—LAYING.

All guns are mounted in such a way that two motions can be given to the axis of the piece, viz., motion in a vertical plane, usually termed elevation; and motion in a horizontal plane, usually termed training. The former is always effected by mechanism, the latter is carried out sometimes by hand and sometimes by mechanism. When a gun is elevated and trained for the purpose of hitting some target, it is said to be "laid."

Causes affecting the Motion of a Projectile.

The motion of a projectile, referred to the vertical plane of departure, is affected by the following causes:—

1. Resistance of the air.
2. The force of gravity.
3. Wind, blowing up or down the line of fire: this, in the case of artillery fire, is usually neglected.

The united effect of 1 and 2 has already been discussed in Chapter II, where it is shown that for given ballistics an angle of tangent elevation can be found for each range.

The motion of the projectile out of the plane of departure referred to the horizontal plane is affected by the following causes:—

1. Drift.

This is an effect observable with all rifled guns, by which the shot is deflected in its flight more or less from the vertical plane of fire; the deflection is to the right when the gun is rifled with a twist on a right-handed screw, to the left with a left-handed twist.

Thus it was found by Mr. Rigby, Superintendent R.S.A.F., Enfield, that with two barrels rifled respectively, with right and left-handed twists, and laid parallel, the bullets struck on a target at 1000 yards on an average 15 inches farther apart than the muzzles, showing that the *drift* of the rifle bullet at this range is about $7\frac{1}{2}$ inches.

In artillery the right-handed twist is always employed; but small arms are now rifled with a left-handed twist.

The drift increases rapidly with the elevation and range of the gun; thus it was found that the 9·2-inch fired at Shoeburyness with an elevation of 40° and a muzzle velocity 2375 f/s, sent a shot weighing 380 lb. to a range of over 20,000 yards, and that the drift was about 1000 yards to the right of the vertical plane of fire.

But the general effect may be attributed to the observed tendency of the projectile to move with its axis nearly tangential to the trajectory.

To keep the point of the projectile continually turning downwards

Digitized by Google

into the tangent of the trajectory, the projectile must be acted upon, as in the case of a top, by a couple whose axis is directed towards the centre of curvature of the trajectory.

This couple will be called into existence if the projectile moves in a slightly sidelong position, with its nose turned a little to the right of the vertical plane of motion; and now the drift may be supposed due to the projectile following its nose to the right, and a deflection to the right of the vertical plane of fire thus accumulates in consequence.

In the case of the new 13-pr. and 18-pr. Q.F. guns, the permanent angle of deflection is given by inclining the cradle trunnions $1\frac{1}{2}°$ to the horizontal, the left trunnion being the lower.

2. Wind.

This effect of wind is usually estimated, and corrected for, when possible, by observation of fire.

3. Want of level, *i.e.*, anything which causes the plane containing the sights to be rotated out of the vertical plane, and so causes deviation between the vertical planes of sight and departure.

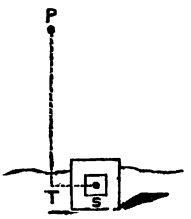
Thus with field, mountain, and certain siege guns, one wheel might, on account of the ground, be higher than the other: a screw gun, such as the 7-pr. of 400 lb. might be "overscrewed," so that the trunnion ring would be rotated out of its proper position; a heavy gun, with or without trunnions, might, owing to some defect in the mounting or platform, be "down on one side."

The effect of this want of level is to deflect the projectile towards the lower side: its extent can usually be ascertained and allowed for. It is mathematically investigated later on.

For given ballistic conditions, drift can usually be measured and allowed for. With the 60-pr. B.L. gun, the adjustment for difference of level of wheels is arranged for by means of cross levels on the rear sight. This will be referred to later.

From the above considerations it is apparent that if it is desired to hit a point S, the axis of the gun must be directed on some higher point P, say, in order to counteract gravity, &c., P being vertically over some point T, say, to the *left* of S, it being supposed that there are some disturbing causes whose united effect would be to deflect the projectile a distance TS to the right of the prolongation of the axis of the piece.

Fig 1.



The virtual effect of travel of target is analagous to the effects that have just been discussed; as the target moves after the gun is laid, its motion between the completion of the laying and the moment the projectile reaches the end of the range must be allowed

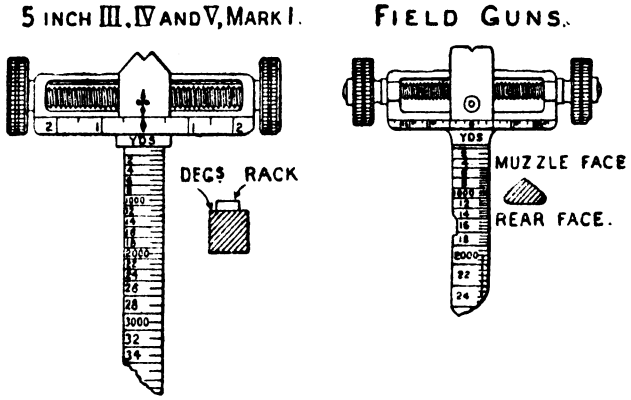
Digitized by Google

for in the laying; the component of this motion, referred to the vertical plane, is allowed for in the elevation, the component referred to the horizontal plane is allowed for in the training.

The Direction of the Line of Sight.

A consideration of the ordinary tangent sight and foresight will demonstrate how the line of sight is practically directed, and will lead up to the consideration of other appliances.

Fig. 2.



The tangent or hind sight consists of a steel bar with a cross head; the bar slides in a socket attached to the gun; it is of triangular or rectangular cross section, and is graduated usually on the rear face in yards and on the front in degrees. The cross head is provided with a sliding deflection leaf, in which is a central notch; the leaf can be moved along a scale right and left of a central zero. The foresight is usually hog-backed or acorn-shaped; as seen from the rear it has practically a triangular cross section.

When the gun is properly laid, the line of sight passes through a point midway between the shoulders of the notch, the apex of the foresight, and the point aimed at.

When the steel bar is run down in the socket to its lowest position it is at zero. If the gun were laid with the tangent sight in this position, the line of sight would be parallel to the axis of the bore, and the gun would be laid "point blank."

When the gun is to be laid on an object at any range, the elevation due to the range must be given; this is effected by raising the tangent scale until the required graduation is level with the top of the socket; then, when the breech is lowered, so that the line of sight may be directed on the object, the angle between the axis of the gun and the line of sight will be the angle due to the range, *i.e.*, the angle of tangent elevation (*vide* fig. 2, Chapter I).

The graduations on the bar which register the elevation given, must first be calculated in degrees; they are determined from the relation

$$l = r \tan \theta,$$

Digitized by Google

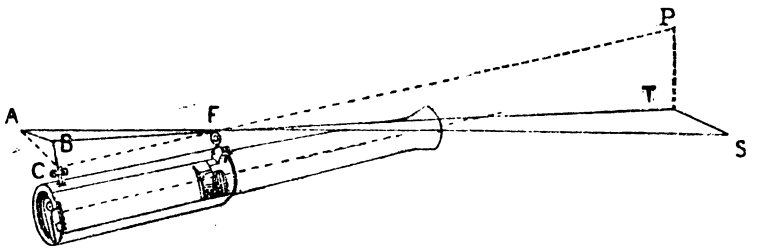
where l is the length in inches from the zero of the scale to the required graduation; r the radius distance in inches and θ the angle of elevation represented by the graduation in question; when the degree graduations are obtained, graduations in yards can be obtained from them by noting the ranges and their corresponding elevations in the range table of the gun.

The socket for the bar of the tangent sight is made so as to give the latter a set to the left; this is done to counteract drift, as will be explained later.

Mathematical Investigation.

The foregoing points with regard to drift and deflection may be considered mathematically as follows :—

Fig. 3.



Let BC in fig. 3 represent a tangent scale raised to the tangent elevation CB required for the distance FT, which may be called the range R; so that, if the plane FBC is vertical, with BF aligned on T, the shot would strike at T in the absence of drift or other lateral disturbance.

But if the shot strikes the vertical tangent through T to one side at S, the horizontal distance TS is called the *drift*, and denoted by D, and the angle TFS is called the *drift-angle*, and denoted by γ suppose.

To align the sights on S, the point struck, deflection BA must be given on a deflection scale, such that

$$\frac{AB}{BF} = \frac{TS}{FT} = \frac{D}{R} = \tan \gamma.$$

Through the fore-sight F draw FC parallel to the axis of the piece; then BFC is the angle of tangent elevation, denoted by E suppose.

If the angle ACB is denoted by θ,

$$\tan \theta = \frac{AB}{BC} = \frac{AB}{BF} \cdot \frac{BF}{BC} = \tan \gamma \frac{1}{\sin E}.$$

But R sin E is practically the same as R tan E or TP in fig. 1 or 3, and TP is practically $\frac{1}{2}gT^2$, the vertical distance fallen by the shot from its original direction of projection FP, in the time of flight T; and as the drift D is found in practice to vary very nearly as the square of the time of flight, the angle θ is very nearly the same for all ranges; it is a small angle, never exceeding 3°.

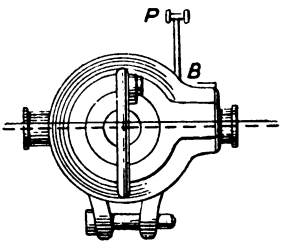
Digitized by Google

Advantage is taken of this circumstance by inclining the slot for the tangent scale laterally in the direction of AC at an average angle θ to the line BC, called the *permanent angle of deflection.*

With howitzers, however, the varying charges prevent the use of a permanent angle of deflection; their tangent scales are therefore perpendicular to the plane through the axis of the piece and the trunnion, and are provided with long deflection bars.

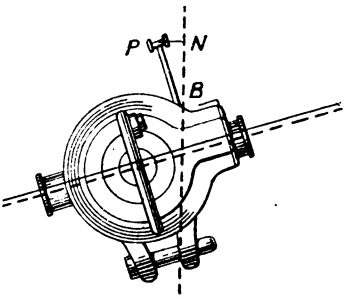
Let PB be the tangent or back sight of a gun whose axletree is level (see fig. 4A), let the angle of elevation be E and the gun laid on to a target T, if now from inequalities or slope of the surface of the ground, or platform, the axis of the trunnions, or the axletree, slopes at an angle β, then if we draw PN perpendicular to NB, which is now drawn vertically downwards through B, the angle PBN is β (see fig. 4B), and the amount of deflection that has been put on to the tangent sight is PN. It is now required to find what number of minutes of deflection this represents, that is, what angle does PN subtend at the foresight.

Fig. 4A.



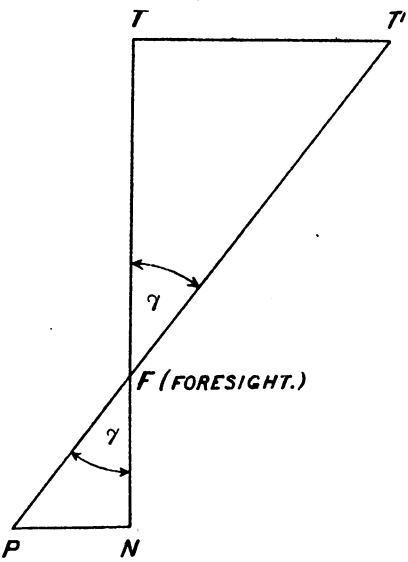
AXIS OF TRUNNIONS HORIZONTAL.

Fig. 4B.



AXIS OF TRUNNIONS NOT HORIZONTAL.

Fig. 4C.



Digitized by Google

From fig. 4B we see that

$$PN = PB \sin \beta$$

$$= h \sin \beta,$$

where h is the length of sight.

In fig. 4C, let F be the foresight and N, P have the same meaning as in fig. 4B, T is the target, then since the angle of elevation is E, we have

$$\frac{\text{length of sight}}{\text{length between back and foresight}} = \tan E \text{ (see p. 75)},$$

i.e.,

$$\frac{h}{l} = \tan E.$$

If γ is the deflection in minutes, then, producing PF to T', then

$$\tan \gamma = \frac{PN}{NF} = \frac{h \sin \beta}{l} = \frac{h \sin \beta}{h \cot E} = \sin \beta \tan E,$$

when E, β, and γ are small, E and β measured in degrees, γ in minutes. Then taking $\pi = 3$, we have

$$\tan \gamma' = \tan\left(\frac{\gamma}{60}\right)^\circ = \frac{\gamma}{60} \cdot \frac{\pi}{180} = \frac{\gamma}{60 \times 60}$$

$$\sin \beta^\circ = \beta \cdot \frac{\pi}{180} = \frac{\beta}{60}$$

$$\tan E^\circ = E \cdot \frac{\pi}{180} = \frac{E}{60}$$

$$\therefore \text{ since } \tan \gamma = \sin \beta \tan E,$$

so

$$\frac{\gamma}{60 \times 60} = \frac{\beta}{60} \times \frac{E}{60},$$

so that, for practical purposes,

$$\gamma' = \beta^\circ \times E^\circ,$$

which establishes the rule that—

> "The product of the slope (β°) of the trunnions in degrees and the elevation (E°), also in degrees, gives the minutes of deflection (γ') to be given to the higher side."

A knot is a speed of one nautical mile (1000 fathoms) per hour, so that with a fathom of 6 feet a knot is 100 feet per minute, or

$$1 \text{ knot} = \tfrac{5}{3} \text{ f/s}.$$

Deflection for speed K (knots) of platform (ship) or target can be found thus:—

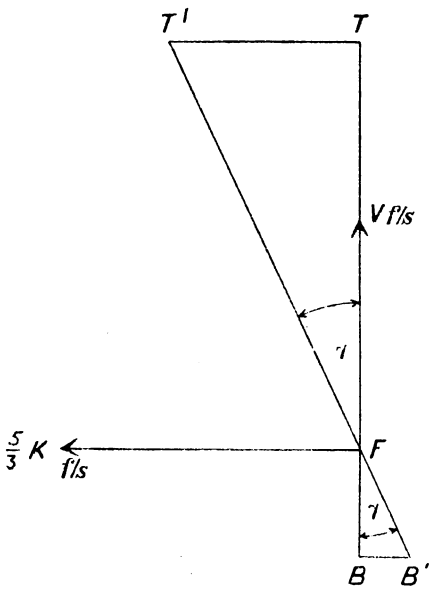
Let T be the target, F the foresight of the gun, and B the tangent or back sight.

Digitized by Google

1st. Suppose the target fixed and that the gun moves as when firing on board a ship whose speed is K knots across the front of the target.

K knots is $\frac{5K}{3}$ f/s.

Fig. 5.



Let the direction in which the ship is moving be as shown, and let V be the muzzle velocity of the shot, then the shot will strike at T', where

$$\tan \gamma = \frac{TT'}{TF} = \frac{\frac{5}{3}K}{V},$$

because the shot moves in the direction FT' on leaving the muzzle of the gun, according to the law of the parallelogram of velocities, *i.e.*, since

$$\angle B'FB = \angle TFT',$$

we have

$$\tan BFB' = \tan \gamma = \frac{BB'}{BF} = \frac{d}{r},$$

$$\therefore \frac{d}{r} = \frac{\frac{5}{3}K}{V},$$

where d is the deflection in inches and r is the distance in inches between the two sights, V is the muzzle velocity.

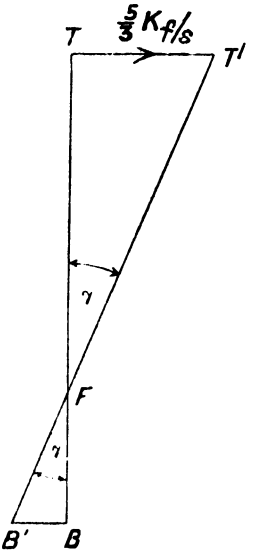
2nd. *Suppose the target moving and the gun fixed.*

If the target (ship) moves with a speed of K knots directly across the front of the gun, then, if the range FT = R yards, and no deflection be given, the shot will strike at T, whilst the target will have moved to T'.

Digitized by Google

If the shot takes t seconds to go from gun to target for a range of R yards, then the average velocity of the shot is

Fig. 6.



$$\text{U f/s} = \frac{3\text{R}}{t}, \quad i.e., \quad 3\text{R} = \text{U}t.$$

The ship travelling at a speed of $\frac{5}{3}$K f/s for t seconds will pass over

$$\text{TT}' = \tfrac{5}{3}\text{K} \,.\, t \text{ feet},$$

and

$$\tan\gamma = \frac{\text{TT}'}{\text{TF}} = \frac{\frac{5}{3}\text{K} \,.\, t}{3\text{R}} = \frac{\frac{5}{3}\text{K}}{\text{U}},$$

and therefore

$$\frac{\text{BB}'}{\text{BF}} = \frac{d}{r} = \tan\gamma = \frac{\frac{5}{3}\text{K}}{\text{U}},$$

where U is the average velocity over the range.

Thus, if r is 3 feet = 36 inches, and V = 2000 f/s, U = 1500 f/s, the length of a graduation d for 10 knots speed is given by

$$d = \frac{36 \times \frac{5}{3} \times 10}{2000 \text{ or } 1500} = 0{\cdot}3 \text{ or } 0{\cdot}4 \text{ inch}.$$

The deflection leaf is made use of to compensate for causes tending to divert the projectile to the left or right, it being a practical rule "never to lay off the target." The scale on the cross head is usually graduated in divisions, each division representing five minutes, on the same scale as the degrees on the tangent bar, and by its aid the notch on the leaf can be set to any required graduation; so that when the gun is laid, its axis will make an angle with the line it would have occupied had the notch remained at zero. Thus, suppose the notch were removed ten minutes to the left, then when the gun is laid its axis will make an angle of ten minutes with the position it would have occupied had the gun been laid with the notch at zero.

Methods of Sighting used in Practice.

The methods of sighting used in the Service may be classed as follows:—

A. By direct vision (tangent elevation);
B. By mechanical indicators or clinometer (quadrant elevation);
C. By automatic sights (tangent elevation and quadrant elevation);
D. By P.F. system.

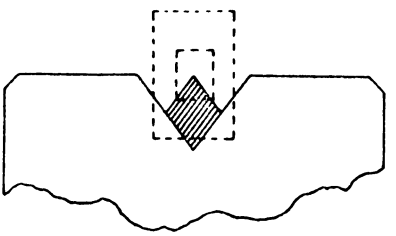
or by a combination of these methods.

A. We use either a tangent sight or a telescope provided with a pointer.

Tangent sights form the oldest system, the line of sight being the prolongation of the line joining two sights, of which the foresight is usually fixed, and of an acorn or other suitable shape, while the back sight is adjustable both vertically and horizontally and carries a notch. The sighting point of this latter is halfway between the top edges of the notch; this point, the top of the fore sight, and the target must be brought absolutely in line.

Such an alignment is called a full sight, see figure.

Fig. 7.



FULL SIGHT.

If the bottom of the notch be employed (termed a fine sight), an error is introduced and the gun is given too little elevation, the extent of the error being the angle subtended by the depth of the notch at the distance between the two sights.

To estimate the extent of this error, consider the notch to be 0·1 inch deep and the distance between the sights 30 inches, then the angular error will be

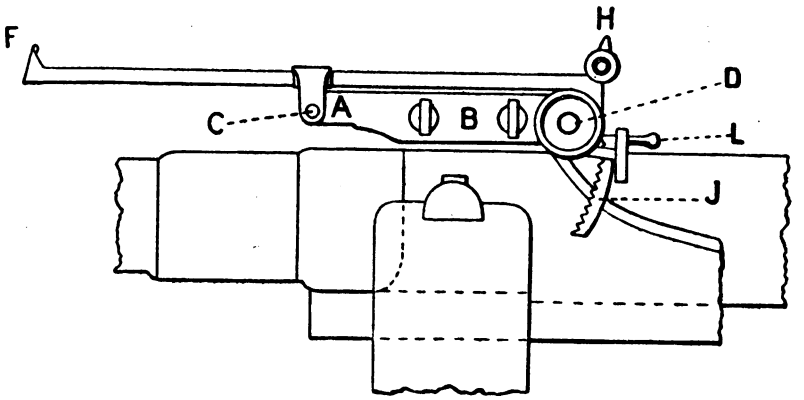
$$\tan^{-1}\frac{1}{300} = \tan^{-1} 0{\cdot}00333 = 12'.$$

When the gun is carried in a cradle, as in Q.F. carriages, a more convenient method of mounting the sights is to place them at either end of a sight bar adjustable laterally, relative to an arm or rocking bar. This rocking bar is pivoted to the cradle so as to be moved in a vertical plane by a miniature elevating gear. This arrangement forms the rocking bar sight of our Service, it is also termed the "Bar and Drum" sight from the fact that the angle of elevation may be read off a drum actuated by the gear. An angular movement of the sight bar for deflection is effected by means of a screw.

Digitized by Google

HF is a bar upon which the hind sight H and the foresight F are mounted; it is pivoted at C; when a handle L is rotated the elevating arc J raises the end H of the bar, so that the latter makes

Fig. 8.



the desired angle of elevation with AB, which is attached to the mounting and is parallel to the axis of the bore. Ranges corresponding to the correct angles of elevation are engraved on the circumference of the drum D, which rotates round an axis perpendicular to that of L and is actuated by a wheel and worm.

This system lends itself to the combination of the telescopic and open sights, the telescope being mounted in carriers attached to the same bar that carries the open sights, the optical axis of the telescope thus remaining parallel to the line of the open sights and the adjustments for elevation and deflection being common to both.

By means of a pointer contained in the telescope the gun may be laid by directing its optical axis on the target alternatively with the use of the open sight.

A similar method was embodied in Scott's sights for Field Artillery, the body of the telescope itself taking the place of the rocking bar, and deflection being given by moving the pointer horizontally. The telescope in this case was pivoted for elevation to a carrier attached to trunnions resting in V-shaped notches on one trunnion, so that it can be levelled and the sighting plane brought vertical irrespective of the difference in level of the wheels.

The Independent Line of Sight.

The most recent arrangement of sights for Field Artillery is the system known as the "independent line of sight;" this is, strictly speaking, a combination of methods A and B, and may best be considered here.

Under this system the line of sight is directed on the target by direct vision irrespective of the angle of elevation required for range. The axis of the piece is set at the correct angle to the line of sight by the aid of a range indicator which reads in degrees or yards. These two adjustments are quite independent of one another, and are performed by different men and different sets of gear. Moreover, they can be performed simultaneously without interfering with each other, or either can precede the other.

Digitized by Google

To embody this principle, therefore, three sets of gear are required:—

I. To move the line of sight relative to the horizontal (angle of sight).

II. To move the gun relative to the line of sight (angle of elevation).

III. To measure and record on a suitable dial the motion given by II.

These requirements can best be applied to a sight of the rocking bar type, which may be provided with both open and telescopic sights.

In the new 13 and 18-pr. Q.F. equipment, the Motions I and II are provided for by employing a double-ended elevating screw, to the middle point of which the rear end of a rocking bar sight is connected by a suitable link. The front end of the rocking bar is pivoted to a prolongation of the left cradle trunnion, the pivot being so inclined as to throw the sighting plane sufficiently out of the vertical to compensate for drift.

The lower half of the screw runs in a nut carried by the carriage, while the cradle runs up and down the upper half of the screw.

A separate indicator measures and records this latter motion.

By attaching a suitable clinometer to the rocking bar and setting it at the observed or calculated angle of sight the Motion I can be applied, though the target be invisible through atmospheric causes or from the conformation of the ground. The gun meanwhile is set at the angle of elevation for range by II, as before, the lateral alignment being obtained by aiming posts. The sights will then be actually pointing at the target, although there may be hills or fog in the way.

The great advantage of the independent line of sight is that it limits the duties of the layer to keeping his sights on the target, such alignment not being disturbed by changes in the angle of elevation, such as occur during ranging or engaging a moving target; these changes only affect II.

The advantages of the system can however be fully reaped only when the gun is allowed a sufficient length of recoil through a cradle to render the latter and the rest of the carriage motionless during recoil.

The sight and elevating gear being attached to the cradle, and not to the gun, do not recoil and allow the layer to follow up a moving target continuously, and not lose sight of one so obscure as to be difficult to pick up.

B Method.

In this system, which is chiefly applied to guns in permanent works, the gun can be set at an angle of quadrant elevation and at any degree of traverse by the aid of mechanical indicators. The latest form of elevation indicator is a graduated circular plate carried by one end of a short shaft. The other end carries a toothed wheel, actuated by a toothed arc, attached to the cradle in which the gun rests. Any motion of elevation given to the gun will cause the plate to revolve past a stationary reader and allow the corresponding graduation in yards to be read off. For varying charges different sets of concentric graduations can be engraved on the plate and the reader clamped to the set required.

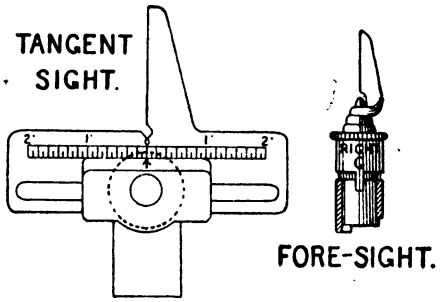
The degree of traverse can be read by the graduations on a ring, in a suitable position round the pedestal in connection with a reader

Digitized by Google

fixed to the carriage. This method is usually employed in connection with the various range finding or position finding systems.

In some cases the elevation indicator only may be employed, the gun being laid for direction by direct vision, making use of straight edged sights for the purpose. Straight edged sights may be described as a tangent sight and foresight with blades attached to them as in the figures:—

Fig. 9.



These blades serve two purposes: they are found to be of use in keeping a gun trained on a moving object, and they obviate the constant altering of the height of the hind sight consequent on change of range, as the blades cover some 1,000 yards of water.

Guns that employ the elevation indicator are always placed at a certain height above the sea. In order therefore to determine the quadrant elevation due to any range, it is necessary to subtract from the tangent elevation, as given in the range table, the angle of depression due to the range; it sometimes happens that the latter angle is greater than the former, so that the quadrant elevation is *minus*, or really *quadrant depression*. When the quadrant elevation due to each 100 yards of range is determined, it is then possible to graduate the rear edge of the elevation indicator in yards, by making the graduations thereon correspond with the degree graduations on the elevation indicator.

Example

6″ B.L. GUN, MARK VII.

Charge 23 lbs. cordite M.D. Size 16.
Muzzle velocity 2493 f/s at 60° F.
Height above Mean Sea Level 100 feet.

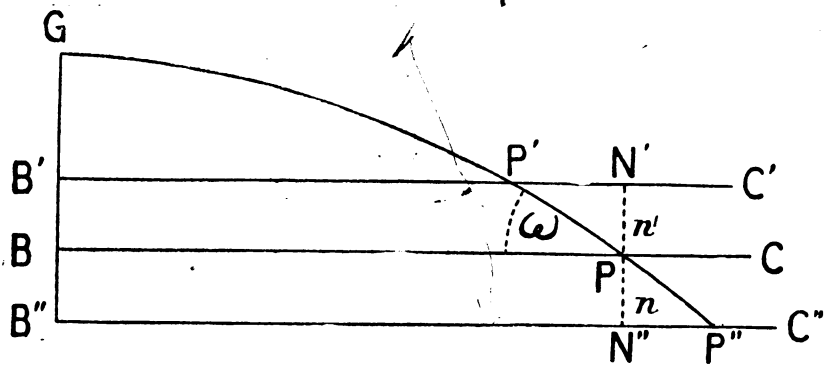
Range in yards.	Tangent elevation.	Angle of depression.	Quadrant angle.
2,000	1° 1′	58′	3′ elevation
4,000	2° 32′	29′	2° 3′ ,,
6,000	4° 46′	19′	4° 27′ ,,
8,000	7° 58′	14′	7° 44′ ,,
10,000	12° 6′	12′	11° 54′ ,,

As owing to the tide the sea level alters from time to time, the *height of a gun above mean tide level* is usually taken as the height

Digitized by Google

of site, and quadrant elevation calculated therefrom, and a "tide correction" applied where necessary, by adding or subtracting from the range given to the gun.

Fig. 10.



Thus let a gun be placed at G, at a height GB above *mean tide* level. Let B' C' be *high water* level and B" C" *low water* level. Then if a gun is correctly laid to strike P, with a quadrant elevation due to a height G B, if it is "high water" it will strike "short" at P', if it is "low water" it will strike at P" and be "over."

Intermediate fluctuations of the tide would have corresponding effects.

The distance P'N' or P"N" evidently depends on the rise or fall of the tide and the angle of arrival at the range in question.

Thus, suppose the level of the water to be n feet above or below mean tide, then for a range R yards and an angle of arrival ω, the *range correction due to tide* would be

$$\tfrac{1}{3}n \cot \omega \text{ (yards)}.$$

Tables of tide corrections are made out to suit local conditions, and in practice the amounts are recorded in multiples of 25 yards.

EXAMPLE.

6" B.L., Mark VII.
Muzzle velocity 2493 f/s.
Height of gun above Mean Sea Level 100 feet.
Difference in height between high water and low water 20 feet.

Correction for low tide is	.. ..	$-\frac{10}{3}\cot\omega$ yards
,, ,, $\frac{1}{4}$ tide is	.. ..	$-\frac{5}{3}\cot\omega$ yards
,, ,, mean tide is	.. ..	nil yards
,, ,, $\frac{3}{4}$ tide is..	.. ..	$+\frac{5}{3}\cot\omega$ yards
,, ,, full tide is	.. ..	$+\frac{10}{3}\cot\omega$ yards,

where ω is the angle of arrival (see page 4) for the range considered.

The angle of descent for any range is got at once from the Range Table of the gun, and the necessary corrections for height of tide are shown in tabular form.

Digitized by Google

Range in yards.	Angle of descent.	Angle of sight.	Angle of arrival.	Correction in yards.				
				Low tide.	Quarter tide.	Mean tide level.	Three-quarter tide.	Full tide.
	° ′	′	° ′					
2,000	1 18	58	2 16	−84·2	−42·1	0	+42·1	+84·2
4,000	3 40	29	4 9	−46·0	−23·0	0	+23·0	+46·0
6,000	8 2	19	8 21	−22·8	−11·4	0	+11·4	+22·8
8,000	14 24	14	14 38	−12·8	− 6·4	0	+ 6·4	+12·8
10,000	22 22	12	22 34	− 8·0	− 4·0	0	+ 4·0	+ 8·0

A clinometer placed on a plane cut on the gun or cradle may be employed in the case of wheeled artillery to lay for elevation when the target is invisible, and its function then becomes similar to that of an elevation indicator.

When, however the target is above the gun, the angle of sight must be added to the angle of tangent elevation, and when the target is below, the angle of sight must be subtracted from the tangent elevation to give the correct quadrant angle of elevation.

This does not apply to the sight clinometer of the independent line of sight, insomuch as this addition or subtraction is performed by setting the sight clinometer to the angle of sight and the range indicator to the angle of elevation.

Method C.

All automatic sights are based on the same principle, namely: that for a given range there is a corresponding T.E. and Q.E., when the ballistic conditions and the height of site are constant.

The following is an example of how this principle may be applied:—FH in fig. 11 is a bar sight, similar to that of fig. 6, which carries an arm CD. C is a pivot carried by AB, a straight piece of metal which always remains parallel to the axis of the bore; the bar carrying the fore and hind sights, F and H, with its attached arm CD, is capable of movement about C, but this movement is governed by the pin D, which moves in the cam ER. The front surface of ER is cut so that when the line of sight HF is directed on an object, the angle between HF and AB will be the T.E. due to the range. This would be the case when the reading of a clinometer placed on FH (which would give the angle of sight or angle of depression), added to the reading of a clinometer placed on AB (which would give the Q.E.), were together equal to the range table angle of T.E., due to the range of the point upon which HF is directed.

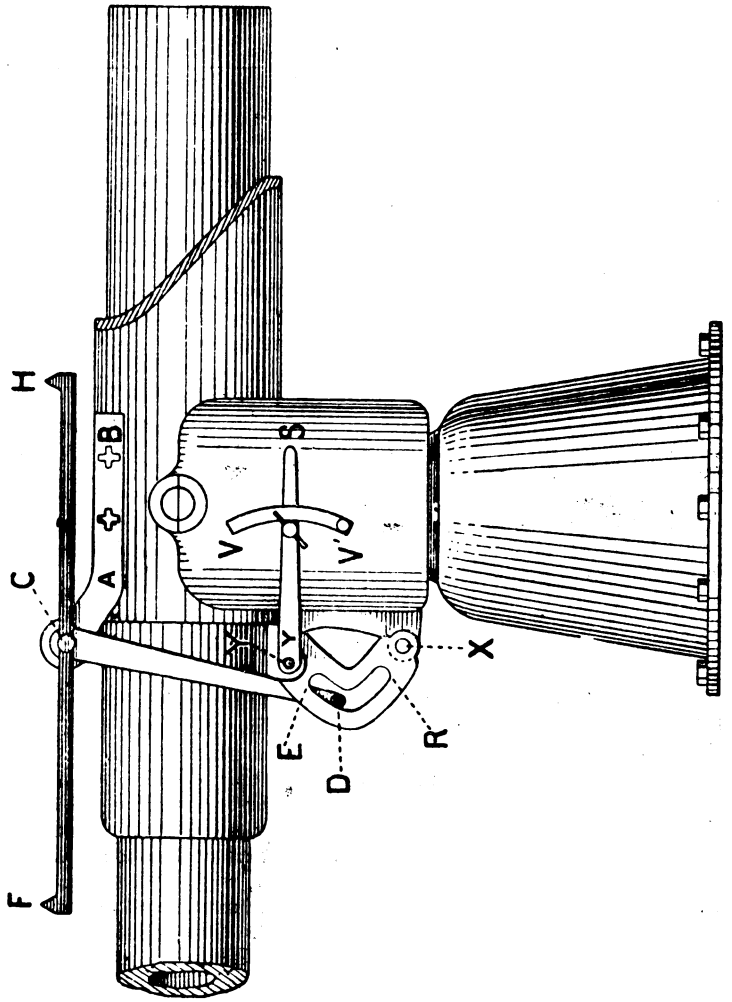
From the above description it is seen that the line of sight and the axis of the piece have relative motion; one cannot be altered without interfering with the other.

Corrections for varying heights of tide are made as follows:—The plate in which the cam ER is cut is pivoted at X, and can be slightly rocked by the action of the handle SY, which can be clamped at any position along the arc VV′, which carries graduations in accordance with local conditions.

Digitized by Google

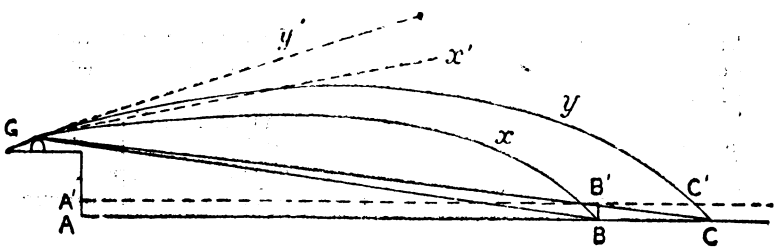
Failure to use the tidal adjustment as the tide rises will cause the shooting to be over, and *vice versâ* on the water level.

Fig. 11.



Assuming that the tide is rising but no tidal adjustment is made let G be the gun at a height GA above mean sea level ABC: B is

Fig.



Digitized by Google

the water line of the target. As the tide rises to A'B'C', the line of the sight bar alters from GB to GB'C, and the trajectory from GxB to GyC'C, and B'C' represents the error "over" due to failure to use the tidal adjustment, and whilst the sight bar turns only through the angle BGB', the gun changes in elevation through the angle $x'Gy'$, which is a much greater angle than BGB', and therefore the trajectory cannot pass through B'.

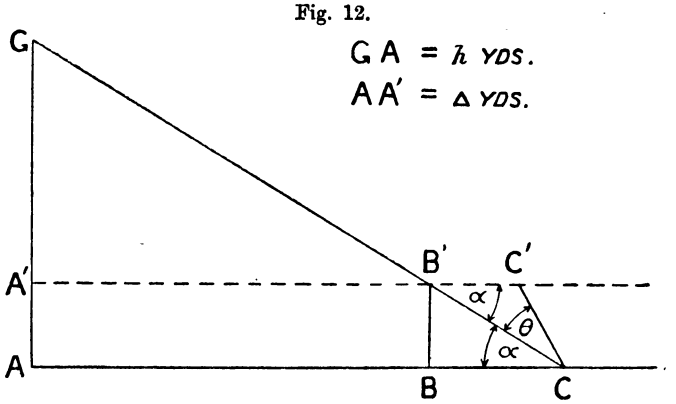
The error

$$B'C' = \frac{\Delta h \operatorname{cosec} \alpha \sin \theta}{\sin (\theta + \alpha)}$$

where

Δh is the difference in yards between the height h yards set on the tide lever and the true height.
θ is the angle of descent for the range.
α is the angle of depression.

Fig. 12.



We have from fig. 12 reproduced, but with heights and angles exaggerated and without lines, x, y, x' y' from fig. 11.

$$B'C' = CC' \frac{\sin \theta}{\sin \alpha}.$$

But

$$CC' = \frac{BB'}{\sin C'CB} = \frac{\Delta h}{\sin (\theta + \alpha)},$$

$$\therefore B'C' = \Delta h \frac{\sin \theta}{\sin \alpha \sin (\theta + \alpha)} = \Delta h \frac{\operatorname{cosec} \alpha \sin \theta}{\sin (\theta + \alpha)}.$$

But we have also

$$\operatorname{cosec} \alpha = \frac{B'C}{BB'} = \frac{GC}{GA} = \frac{R}{h},$$

where R is the range in yards.

$$\therefore \text{error} = \frac{\Delta h}{h} . R . \frac{\sin \theta}{\sin (\theta + \alpha)},$$

and the fraction

$$\frac{\sin \theta}{\sin (\theta + \alpha)}$$

increases as θ increases, that is, increases with the range.

Digitized by Google

From the equation

$$\text{error} = \frac{\Delta h}{h} \cdot \text{R} \cdot \frac{\sin \theta}{\sin (\theta + \alpha)}$$

we see that

error increases as the tide rises;
" " " range increases;
" decreases " height of side h increases.

Moreover, the lower the velocity of the gun the greater are the angles of descent θ, hence the error is also increased with a gun having a low muzzle velocity.

Method D.

As this method may practically be considered as entirely instrumental, it need not be further discussed here; full descriptions will be found in the Manual of Position Finding.

Digitized by Google

Theory of Range Finding.

The range R of a distant object C to the front of a measured base A B of length c is taken as

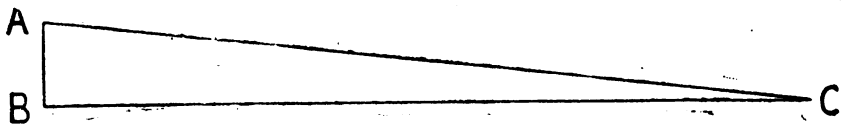
$$c \text{ cosec } C;$$

when the angle of convergence C of the lines of sight AC and BC, in other words the *parallax* of C, has been measured:

$$c \text{ cosec } C$$

is the diameter of the circle round ABC: the letters and notation employed in Trigonometry are employed here for the moment.

Fig. 13.



If the angle C is small, as in practice, and is expressed in degrees or minutes, we can put

$$\sin C = \frac{C^\circ}{57{\cdot}3}, \text{ or } \frac{C'}{3438},$$

and then

$$R = 57{\cdot}3\,\frac{c}{C^\circ}, \text{ or } 3438\,\frac{c}{C'},$$

giving the range R in yards, if c is measured in yards; but if c is measured in feet,

$$R = 1146\,\frac{c}{C'};$$

this is the formula of p. 5 used with the D.R.F., in which case the base AB is vertical, and ABC is a right angle, and AC is the range R.

But with field range finders, such as the mekometer, or the Barr and Stroud range finder, the base AB is horizontal.

Range finders differ from position finders in that they can only measure the distance from the point they occupy to the object. Many range finders are movable and can be used in close proximity to the guns, but a depression range finder must be in a chosen position, and sometimes is at a considerable distance from the guns it serves, consequently ranges as measured by it will not be true for the guns, until a correction called a "group difference" is applied.

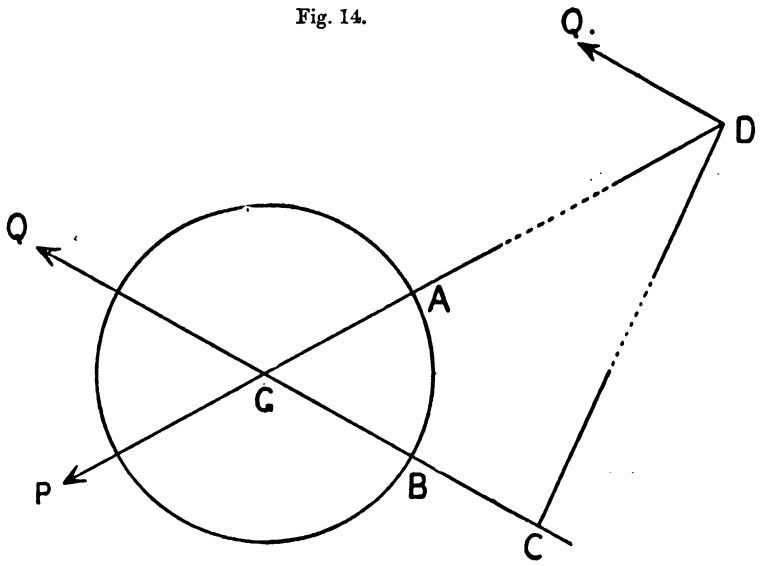
The group difference depends on "displacement" and the angle at which the guns are trained.

The guns of a fort are formed into groups, consisting of one or more guns: in the latter case a gun is selected to be the pivot gun. "Displacement" is the distance in yards between the pivot of the D.R.F. and the pivot of the group it serves. Sometimes two or more groups are served by the same instrument: the displacement must be measured in each instance.

Digitized by Google

A consideration of fig. 14 will make apparent the effect of the training on group difference.

Fig. 14.



Let G be the pivot gun and AB the circular training arc; let D be the position of the D.R.F. Then GD will be the displacement. Draw the line DAGP; then if the gun and range finder be directed on the line DP, it is evident that the range measured by the instrument will exceed the range from the gun by a distance GD, *i.e.*, the displacement.

Now let the gun be trained through 60° say, so that the pointer on the mounting moves from A to B. Draw the line QGBC, and let DC be a perpendicular on this line from D.

As the ranges measured are great compared with the displacement, the lines of sight GQ and DQ, from gun and instrument respectively, may be assumed to be parallel, and the group difference is given by GC, when

$$GC = GD \cos AGB,$$

so that in this instance it is half the displacement.

In practice group differences are always tabulated in multiples of 50 yards (see G.A. Training, 1905, Vol. II, p. 127).

SECTION II.—ACCURACY OF FIRE.

For good shooting there are two essential requirements: first, a good weapon and good ammunition; and, secondly, men who know how to use them.

But after all care has been taken, absolute certainty of hitting the same spot at each round is impossible, as several causes of error exist, which cannot be avoided.

Accuracy of fire is thus a comparative term; it is said to be good when a group of projectiles fall close together.

Causes of Inaccuracy.

The **chief causes of unavoidable inaccuracy**, which may exist on the experimental practice ground, where all the conditions are most favourable, are as follows:—

1. Want of accuracy in the gun, faulty ammunition, or unsuitable mounting.
2. Weather.

Range and Accuracy.

With the object of compiling Range Tables, a gun of each nature, when introduced into the Service, is sent to Shoeburyness, and series of rounds are fired at several different elevations for **range and accuracy**, with its service ammunition.

Five or more rounds are fired at each elevation.

Mean ranges and mean lateral deviation from the line of fire are then obtained for each elevation; the difference of each round from the *mean* gives the *error*, from which the 50 % zones are worked out.

To take a practical example:—

EXAMPLE I.

No. of round.	Range.	Differences from mean, or errors.	Deviation right.	Differences from mean or errors.	Elevation.
	yds.	yds.	yds.	yds.	
1	4968	23	24·4	3·0	5° 26′
2	4954	9	21·6	0·2	..
3	4962	17	22·8	1·4	..
4	4908	37	20·0	1·4	..
5	4934	11	18·4	3·0	..
Total ..	24726	97	107·2	9·0	
Mean ..	4945	19·4	21·4	1·8	

The second column in the above table gives the actual ranges. The mean range is obtained by adding all together and dividing by 5, since 5 rounds were fired.

Digitized by Google

The third column contains the *difference* of each round, irrespective of sign, from the mean range just found. The mean of these differences is then obtained, and called the mean error in range or mean longitudinal error.

The fourth column gives the lateral deviation from the line of fire. The mean deviation is at the bottom of this column.

And the fifth column gives the differences from this mean, with a mean at the bottom called the mean error in deviation or mean lateral error.

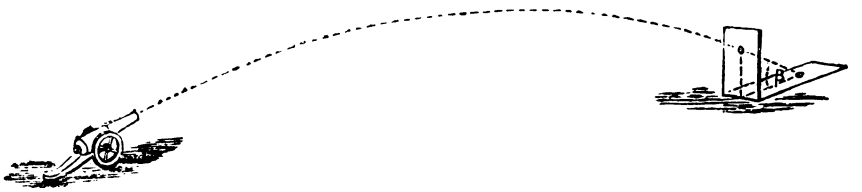
Collecting the results from the Table A we have—

Mean range	**4945**	**yards.**
Mean longitudinal error	**19·4**	**„**
Mean deviation right	**21·4**	**„**
Mean lateral error	**1·8**	**„**

When the position of the point of mean impact on the horizontal plane is known, fig. 15 shows how the magnitude of the angle of descent determines the position of the point of mean impact on a vertical target.

Thus if β be the angle of descent, and if the horizontal target is struck at a distance l from the vertical one, the latter will be struck at a height which equals $l \tan \beta$.

Fig. 15.



The angle of descent of the 8-inch projectile at 4945 yards is known to be 7° 25′.

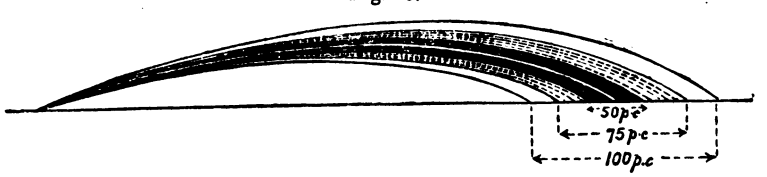
$$\therefore \textbf{Mean vertical error} \ldots\ldots = 19{\cdot}4 \tan 7^\circ 25' = \textbf{2·5 yards.}$$

Vertical targets are employed at the shorter ranges, because they may then be of moderate size, and errors due to inequalities of the ground are eliminated, but at long ranges targets cannot generally be made large enough to catch all the rounds.

The **point of mean impact** on a horizontal target is the intersection of the lines of mean longitudinal and mean lateral deviation, and on a vertical target it is the intersection of the lines of mean vertical and lateral deviation.

The **mean trajectory** is that which strikes the point of mean impact: it is the central one of all the trajectories fired at the same elevation.

Fig. 16.



Digitized by Google

In fig. 16 the central white line represents the mean trajectory, the dark band is that in which 50 °/₀ of the trajectories lie; the shaded band is that which contains 75 °/₀, while the outer band contains the remainder. The width of these bands is exaggerated in fig. 16, for the sake of showing them clearly.

A practical illustration of dispersion or want of accuracy is given by a fire-hose, in which the stream of water is more separated at the end than at the beginning of its course through the air: the whole trajectory being a kind of bent cone, with its apex at the nozzle.

The Range Table 50°/₀ *Zones.*

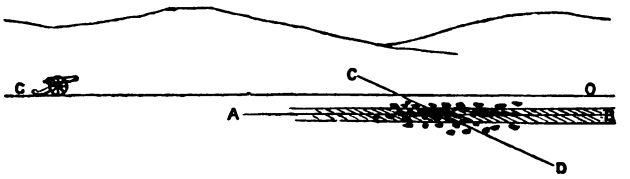
The mean longitudinal error × 1·69 is taken as the width of the 50 °/₀ **length zone**; the mean lateral error × 1·69 is taken as the width of the 50 °/₀ **breadth zone**; the mean vertical error × 1·69 is taken as the width of the 50 °/₀ **height zone.**

The factor 1·69 depends on the Theory of Probability explained in Part II.

Thus, if GO, figs. 17 and 18, represents the direction of the gun, and AB is a straight line parallel to it, at a distance equal to the mean

Fig. 17.

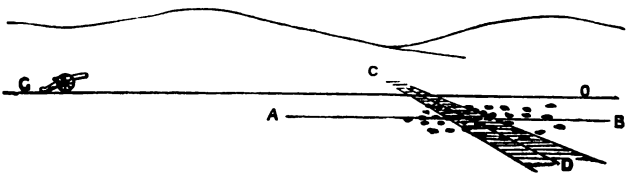
Showing 50 °/₀ breadth zone.



lateral deviation, and CD be a straight line at right angles to GO or AB, at a distance from the muzzle equal to the mean range; then if the zone in fig. 17, called the breadth zone, and that in fig. 18

Fig. 18.

Showing 50 °/₀ length zone.

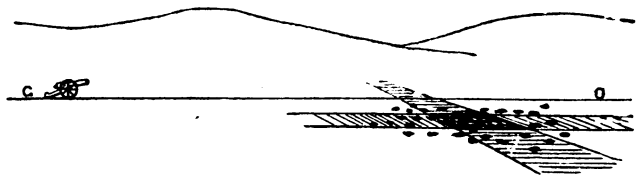


called the length zone, each contains 50 °/₀ of the hits on the surface of the ground, their widths must be 1·69 times the mean lateral error, and 1·69 times the mean longitudinal error respectively. AB and CD are the central lines of these zones.

Digitized by Google

Fig. 19.

Showing 50 °/₀ length zone and 50 °/₀ breadth zone intersecting and forming 25 °/₀ rectangle.



If now we look at fig. 19, where these zones are superposed, we see a rectangle which must contain 50 °/₀ of 50 °/₀, or 25 °/₀ of the total number of hits. In a similar manner a 25 °/₀ rectangle on a vertical target is made up of the intersection of the 50 °/₀ breadth and height zones.

At each range there is a horizontal and a vertical 25 °/₀ rectangle; the width of each is the same, as each has the same breadth zone, but the relation of the length of one to the height of the other depends on the angle of descent.

TABLE A.

PROBABILITY FACTORS.

Per cent.	Factor.	Per cent.	Factor.	Per cent.	Factor.	Per cent.	Factor.	Per cent.	Factor.
1	0·02	21	0·40	41	0·80	61	1·27	81	1·94
2	0·04	22	0·41	42	0·82	62	1·30	82	1·98
3	0·06	23	0·43	43	0·84	63	1·33	83	2·03

11	0·20	31	0·59	51	1·02	71	1·57	91	2·52
12	0·22	32	0·61	52	1·04	72	1·60	92	2·60
13	0·24	33	0·63	53	1·07	73	1·64	93	2·69
14	0·26	34	0·65	54	1·09	74	1·67	94	2·78
15	0·28	35	0·67	55	1·12	75	1·71	95	2·91
16	0·30	36	0·70	56	1·14	76	1·74	96	3·04
17	0·32	37	0·72	57	1·17	77	1·78	97	3·22
18	0·34	38	0·74	58	1·19	78	1·82	98	3·45
19	0·36	39	0·76	59	1·22	79	1·86	99	3·82
20	0·38	40	0·78	60	1·25	80	1·90	100	

This Table A is calculated on the Theory of Probability explained in Part II.

Taking the width of a 50 °/₀ zone as unity, the factor in the above table is the width of the zone containing the corresponding percentage: thus the 80 °/₀ and 20 °/₀ zone is respectively 1·90 and 0·38 times the width of the 50 °/₀ zone.

If the width of the 50 °/₀ zone is given in yards, the widths of other zones containing different percentages can be obtained by *multiplying* by their corresponding factors: thus, if the width of a 50 °/₀ zone is 3 yards, the widths of 25 °/₀ and 72 °/₀ zones are 0·47 × 3 = 1·41 yards and 1·60 × 3 = 4·80 yards, respectively.

Digitized by Google

Conversely, if it is required to find what percentages will fall in zones of given widths, the factors must be obtained by *dividing* each by the width of the 50 °/₀ zone.

Thus, with the same 50 °/₀ zone (3 yards wide) as before, what percentages will fall in zones 2 yards and 6 yards wide?

The factors are

$$\tfrac{2}{3} = 0{\cdot}67 \text{ and } \tfrac{6}{3} = 2{\cdot}00,$$

and they correspond to

$$35\ ^{\circ}/_{\circ} \text{ and } 82{\cdot}4\ ^{\circ}/_{\circ}$$

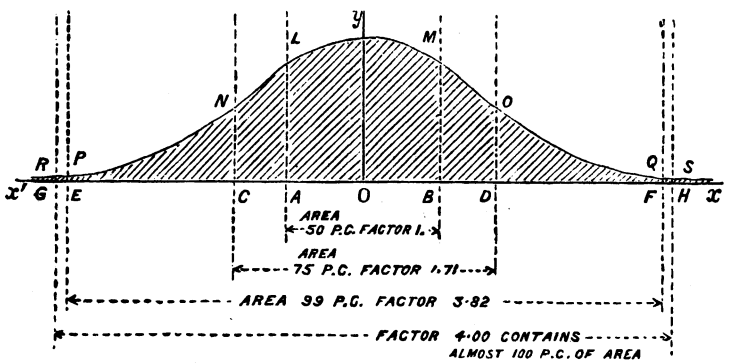
respectively.

The annexed fig. 20 represents the probability curve, the line GH being asymptotic to it; the total area contained between the curve and the line GH is proportional to the total number of rounds, or 100 °/₀.

The central area ABML represents half the total area, or 50 °/₀ of the rounds fired.

Areas of different widths contain percentages according to the table, the widths being the same as the factors in the table: thus the 75 °/₀ area, CDON, is 1·71 times as wide as the 50 °/₀ area, and the 99 °/₀ area, EFQP, is 3·82 times as wide; it is a fair approximation to assume that an area four times as wide as the 50 °/₀ area contains all the area, though there is a small portion outside.

Fig. 20.



The curve of error in fig. 20 can be imitated experimentally in an instrument (fig. 21), invented by Mr. Francis Galton, and called by him the *Quincunx*, from the Latin word used to describe the arrangement in the planting of trees, which is imitated by the pins in this instrument.

A charge of small shot (or better, of spherical seeds, as not so heavy) is allowed to pour through the funnel at the top. The spherules knock against the pins and are scattered thereby in an arbitrary manner; but it is found that they group themselves in the stalls at the bottom in a manner which imitates closely the profile of the Probability Curve.

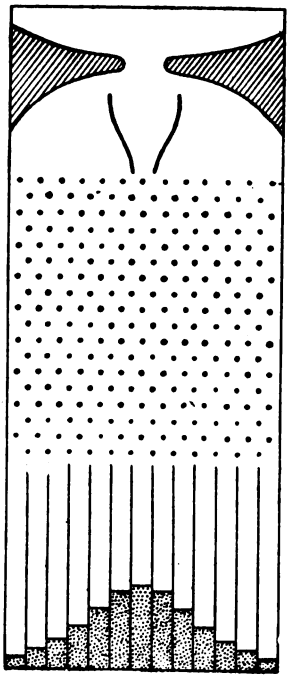
Fig. 21.



Examples on the use of Table A.

Example 1.

If a zone of a certain width catches 20 °/₀ of the rounds fired, how much wider must another be to catch 80 °/₀?

From the Table we find that the 20°/₀ zone is 0·38 of the width of the 50 °/₀ zone; and also that the 80 °/₀ zone is 1·9 times the width of the same standard.

Consequently the widths of the zones in question must be to each other as

0·38 : 1·9, or as 1 : 5,

or the 80 °/₀ zone is five times as wide as the 20 °/₀ zone

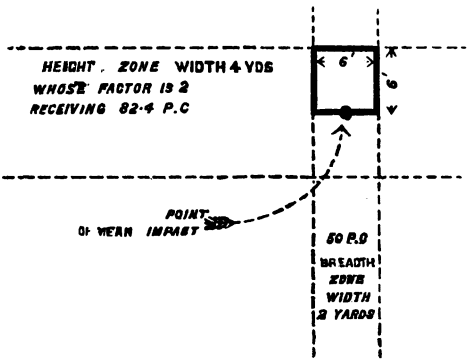
Example 2.

If the breadth and height 50 °/₀ zones are each 2 yards wide, what percentage of hits may be expected on a target 6 feet square, if the point of mean impact is in the middle of the lower edge?

The 50 °/₀ breadth zone just includes the target (fig. 22).

Digitized by Google

Fig. 22.



The height zone to be employed must be one which is double the height of the target, for then the point of mean impact will be in the middle of the zone, and the whole of the target will be included. The factor for this zone is evidently 2, corresponding to a percentage of 82·4: but as the target only lies on one half side, we must take half the percentage or 41·2 %.

Consequently on the target we have

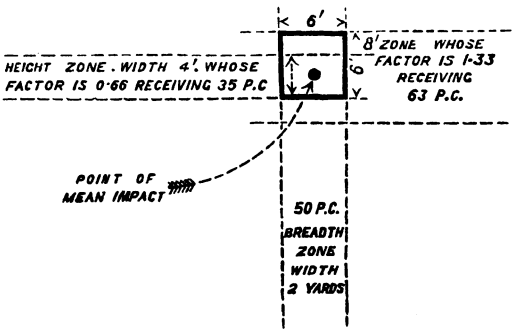
$$50\ \%\ \text{of}\ 41{\cdot}2\ \% = 20{\cdot}6\ \%.$$

EXAMPLE 3.

If in the last example the point of mean impact is raised 2 feet, what improvement may be expected in the shooting?

As before, the 50 % breadth zone just includes the target (fig. 23).

Fig. 23.



For the height zones—take one 4 feet wide and another 8 feet wide. Then the target will be contained in the lower half of the 4-feet zone and in the upper half of the 8-feet height zone.

Digitized by Google

The 4-feet zone has a factor $\frac{4}{6} = 0{\cdot}67$, and it receives

35 °/₀ hits.

The 8-feet zone has a factor $\frac{8}{6} = 1{\cdot}33$, and it receives

63 °/₀ hits.

As the height band, which just contains the target, is composed of the halves of these two zones, it must receive $\frac{1}{2} \times 35 + \frac{1}{2} \times 63 = 49$ °/₀ hits;

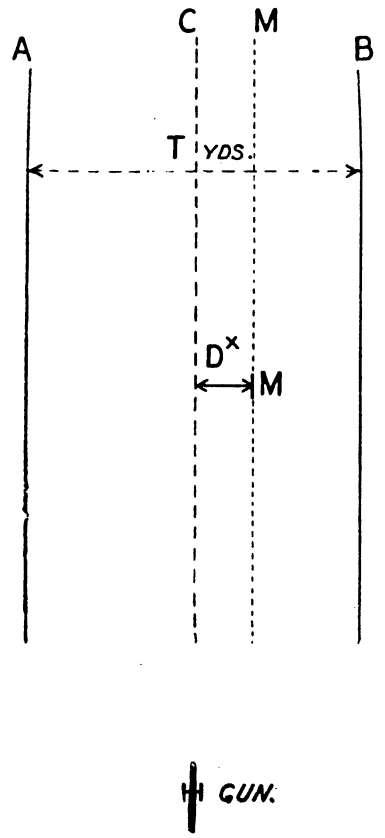
and the whole target has 50 °/₀ of 49 °/₀ = 24·5 °/₀

—an improvement of 3·9 °/₀ of the total fired, or 19 °/₀ more hits on the target than in the last case, for

$$\frac{3{\cdot}9}{20{\cdot}6} = \frac{19}{100} \text{ nearly.}$$

A general method will now be shown for dealing with the case when the mean point of impact is not at the centre of a given zone: the method will be found to be at once applicable to the case where there are many targets and the mean point of impact is at any point.

Fig. 24.



Digitized by Google

Referring to Table A, p. 94, we see at once from the table that if the 50 % width zone at a certain range is P yards, and the width of the target be T yards, then on this target we should obtain a percentage given by Table A against the fraction $\frac{T}{P}$, provided the mean point of impact be on the centre line of the width zone.

Thus if T be 15 yards and P is 20 yards,

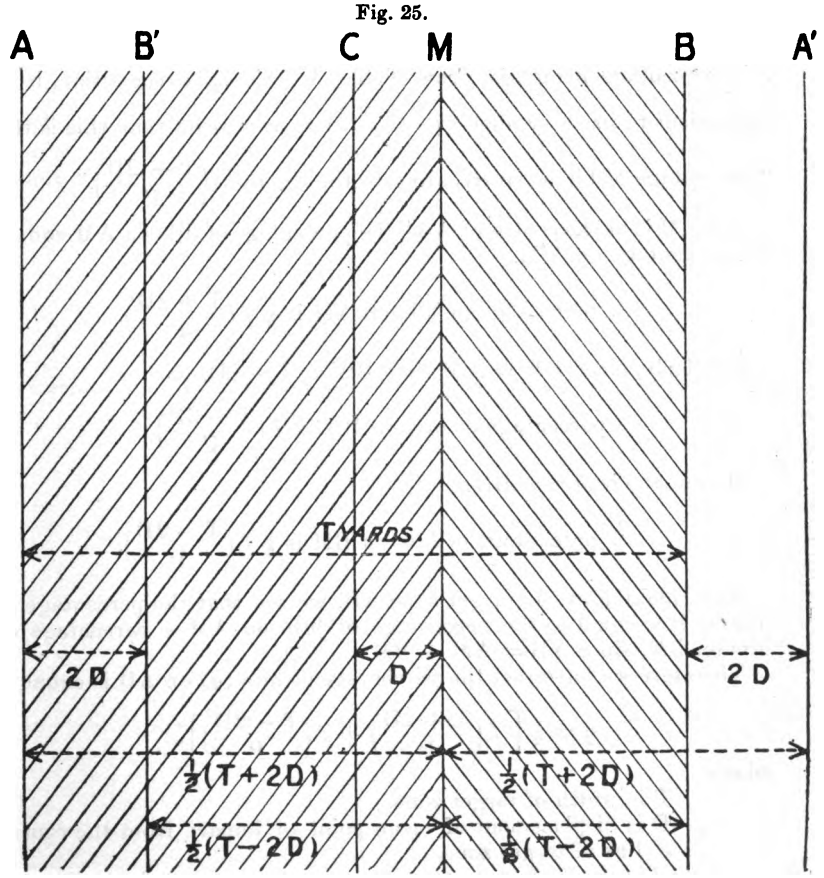
$$\frac{T}{P} = \frac{15}{20} = 0{\cdot}75,$$

and the percentage of hits should be 38·5.

But now suppose the mean point of impact to be not on the centre line of the width zone, but to be D yards (see fig. 24) to one side of it, in this case the percentage will not be 38·5.

We will now proceed to find a method by which we can find the percentage of hits on a zone when the mean point of impact is to one side of the centre line of the zone.

Fig. 25.



Suppose the target width AB is T yards, C is the centre line, and M the line through the mean point of impact, distant D yards from C. Take the line B' distant 2 D yards from A, and A' a similar distance from B (fig. 25).

Digitized by Google

The problem now is, "Find the percentage of hits to be expected on a zone T yards wide, mean point of impact D yards from the centre, given 50 % zone = P yards."

We have

$$AB = T \qquad AA' = T + 2D$$
$$AC = CB = \frac{T}{2} \qquad BB' = T - 2D$$
$$CM = D$$
$$AB' = A'B = 2D$$

so that
$$AM = MA' = \tfrac{1}{2}(T + 2D)$$
$$BM = B'M = \tfrac{1}{2}(T - 2D).$$

Therefore the zone AA' of width (T + 2D) and which has the mean point of impact M at its centre will catch a percentage of hits corresponding to the fraction

$$\frac{T + 2D}{P},$$

this percentage being got from Table A. To save repetition, it is convenient to use a symbol $f\left(\frac{T + 2D}{P}\right)$ to represent that this is the "percentage of hits corresponding to the fraction $\left(\frac{T + 2D}{P}\right)$."

Since M is at the centre of AA', the percentage of hits on AM equals the percentage on A'M,

$$\therefore \text{ percentage of hits on AM is } \tfrac{1}{2} f\left(\frac{T + 2D}{P}\right).$$

Similarly, since BM = B'M and BB' = T − 2D, so

$$\text{percentage of hits on BB' is } f\left(\frac{T - 2D}{P}\right).$$

M is at the centre of BB',

$$\therefore \text{ percentage of hits on BM is } \tfrac{1}{2} f\left(\frac{T - 2D}{P}\right).$$

Now, looking at the target zone AB, we see that the percentage of hits on it is equal to the percentage of hits on AM + percentage of hits on BM, since AB = AM + BM.

Therefore we have that the percentage of hits (q) on AB is equal to

$$q = \tfrac{1}{2}\left[f\left(\frac{T + 2D}{P}\right) + f\left(\frac{T - 2D}{P}\right)\right],$$

where

T is width of target zone,
D is displacement of mean point of impact from the centre line of target zone,
P is the 50 % zone,
f means "percentage of hits corresponding to the factor after it," and is found by Table A, page 94.

Examples are now worked out to show the use of this formula and of Table A.

Digitized by Google

It is seen, at once, that if D = 0,

$$q = \tfrac{1}{2}\left[f\left(\frac{T}{P}\right) + f\left(\frac{T}{P}\right)\right] = f\left(\frac{T}{P}\right),$$

which defines Table A.

EXAMPLE 1.

If a zone of a certain width catches 20 % of the rounds fired, how much wider must another be to catch 80 %?

From Table A, opposite 20 %, is the fraction 0·38,
" " " 80 %, " " 1·90.

These figures mean that the

20 % width zone = 0·38 × the 50 % width zone,
80 % " = 1·9 × " " "

the point of mean impact being in the middle of the zone.

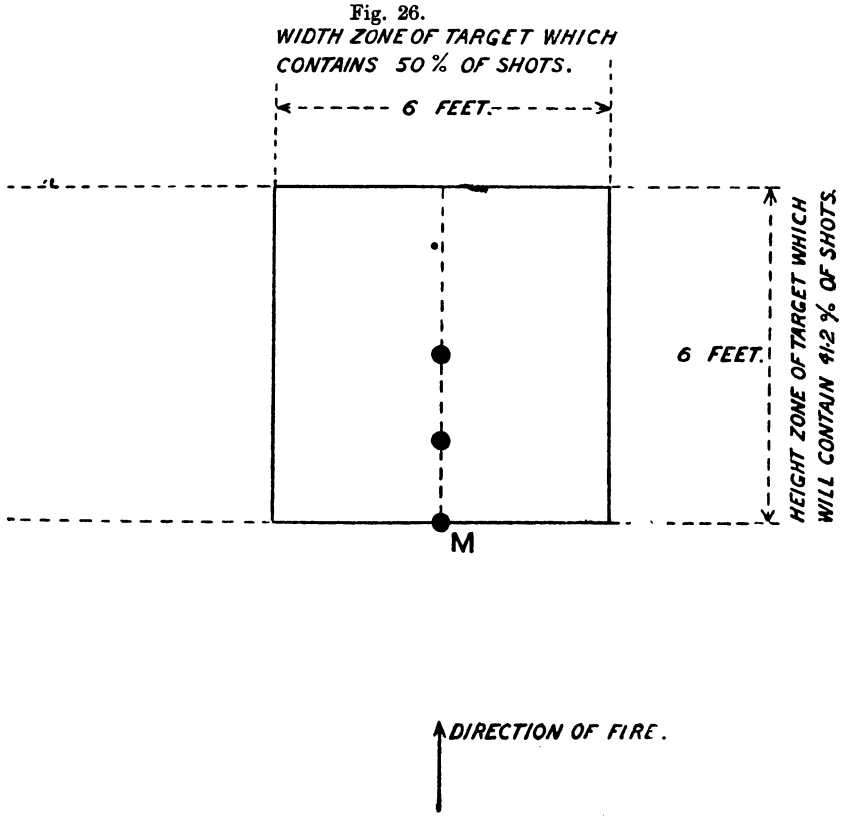
$$\therefore \frac{80\ \%\ \text{zone}}{20\ \%\ \text{zone}} = \frac{1{\cdot}9}{0{\cdot}38} = \frac{5}{1},$$

∴ 80 % zone is five times as wide as the 20 % zone.

EXAMPLE 2.

If the breadth and height 50 % zones are each 2 yards wide, what percentage of hits may be expected on a target 6 feet square, if the point of mean impact is in the middle of the lower edge?

Fig. 26.



Digitized by Google

Consider first the width zone; here the mean point of impact is at the middle of the zone, hence $D = 0$; we have

$$\begin{aligned} \text{Width of target zone} &= T_1 = 6 \text{ feet}, \\ \text{Displacement} &= D_1 = 0 \quad ,, \\ 50\ \%\ \text{width zone} &= P_1 = 6 \quad ,, \end{aligned}$$

$\therefore$ the percentage of hits on the width zone is seen at once to be

$$q_1 = f\left(\frac{T_1}{P_1}\right) = f\left(\frac{6}{6}\right) = f(1) = 50\%.$$

For the height zone, the displacement of the mean point of impact from the centre is 3 feet, hence

$$\begin{aligned} \text{Width of height zone} &= T_2 = 6 \text{ feet}, \\ \text{Displacement} &= D_2 = 3 \quad ,, \\ 50\ \%\ \text{height zone} &= P_2 = 6 \quad ,, \end{aligned}$$

$\therefore$ percentage of hits on the height zone is

$$\begin{aligned} q_2 &= \tfrac{1}{2}\left(f\frac{T_2 + 2D_2}{P} + f\frac{T_2 - 2D_2}{P}\right) \\ &= \tfrac{1}{2}\left(f\frac{6+6}{6} + f\frac{6-6}{6}\right) = \tfrac{1}{2}\left[f(2) + f(0)\right], \\ &= \tfrac{1}{2} \text{ of } 82{\cdot}4, \\ &= 41{\cdot}2\ \%. \end{aligned}$$

Consequently on the target there will be a percentage of hits

$$Q = q_1 q_2,$$

so that

$$\begin{aligned} Q &= 50\ \% \text{ of } 41{\cdot}2\ \%, \\ &= 20{\cdot}6\ \%. \end{aligned}$$

Example 3.

If in the last example the mean point of impact is raised 2 feet, what improvement may be expected in the shooting?

As before, the 50 % breadth zone will catch 50 % of the shots, so that $q_1 = 50\ \%$.

For the height zone we have (see fig. of Ex. 2)

$$\begin{aligned} T_2 &= 6 \text{ feet}, \\ D_2 &= 1 \text{ foot}, \\ P &= 6 \text{ feet}. \end{aligned}$$

$$\begin{aligned} \therefore q_2 &= \tfrac{1}{2}\left[f\left(\frac{T_2 + 2D_2}{P}\right) + f\left(\frac{T_2 - 2D_2}{P}\right)\right], \\ &= \tfrac{1}{2}\left(f\frac{6+2}{6} + f\frac{6-2}{6}\right), \\ &= \tfrac{1}{2}\left(f\,1{\cdot}333 + f\,0{\cdot}666\right), \\ &= \tfrac{1}{2}\left(63\ \% + 34{\cdot}5\ \%\right), \\ &= \tfrac{1}{2} \text{ of } 97{\cdot}5 = 49\ \%. \end{aligned}$$

Digitized by Google

$\therefore$ on the target there will be

$$Q = q_1 q_2 = 50\ ^{\circ}/_{\circ} \text{ of } 49\ ^{\circ}/_{\circ} = 24{\cdot}5\ ^{\circ}/_{\circ} \text{ of hits.}$$

The improvement in shooting is therefore

$$24{\cdot}5 - 20{\cdot}6 = 3{\cdot}9\ ^{\circ}/_{\circ}$$

of the total fired, or 19 °/₀ more hits on the target than in the last case, for

$$\frac{3{\cdot}9}{20{\cdot}6} = \frac{19}{100} \text{ nearly.}$$

EXAMPLE 4.

Suppose there are two targets, 6 feet wide, and of the same height, 3 feet apart, fired at by a gun at a certain range; the width of the 50 °/₀ breadth zone being 6 feet.

Which plan will give the most hits on a target—

(1.) If the mean point of impact is at the middle of one?

(2.) If it is midway between the two?

Taking the first supposition (fig. 27)—

(Neglecting height errors, which bear the same proportion throughout.)

Case (1)—

For target A.	For target B.
T = 6 feet	T = 6 feet
D = 0 ,,	D = 9 ,,
P = 6 ,,	P = 6 ,,

D = 0 show at once that 50 °/₀ of shots will fall on A since

$$\frac{T}{P} = 1.$$

$$q = \tfrac{1}{2}\left(f\frac{6+18}{6} + f\frac{6-18}{6} \right),$$

$$= \tfrac{1}{2}\left[f(4) - f(2) \right],$$

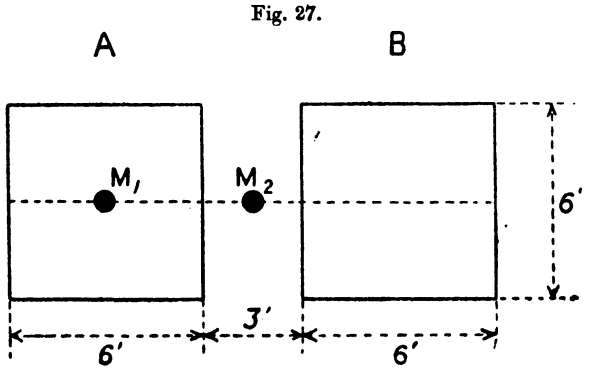
$$= \tfrac{1}{2}\,(100\ ^{\circ}/_{\circ} - 82{\cdot}4\ ^{\circ}/_{\circ}),$$

$$= 8{\cdot}8\ ^{\circ}/_{\circ}.$$

Therefore there will be on both A and B breadth zones

$$50 + 8{\cdot}8 = 58{\cdot}8\ ^{\circ}/_{\circ}.$$

Fig. 27.



Digitized by Google

Case (2)—

The mean point of impact being exactly midway between the targets A and B, there will be the same percentage of hits on A as on B, therefore percentage of hits on A and B = twice the percentage of hits on A.

For target A.

$$T = 6 \text{ feet}$$
$$D = 4{\cdot}5 \text{ ,,}$$
$$P = 6 \text{ ,,}$$
$$\therefore q = \tfrac{1}{2}\left[f\left(\frac{6+9}{6}\right) + f\left(\frac{6-9}{6}\right)\right],$$
$$= \tfrac{1}{2}\left[f(2{\cdot}5) - f(0{\cdot}5)\right],$$
$$= \tfrac{1}{2}(90{\cdot}7\ \% - 26{\cdot}5\ \%),$$
$$= \tfrac{1}{2}(64{\cdot}2\ \%).$$

$\therefore$ percentage of hits on A and B together is

$$64{\cdot}2\ \%.$$

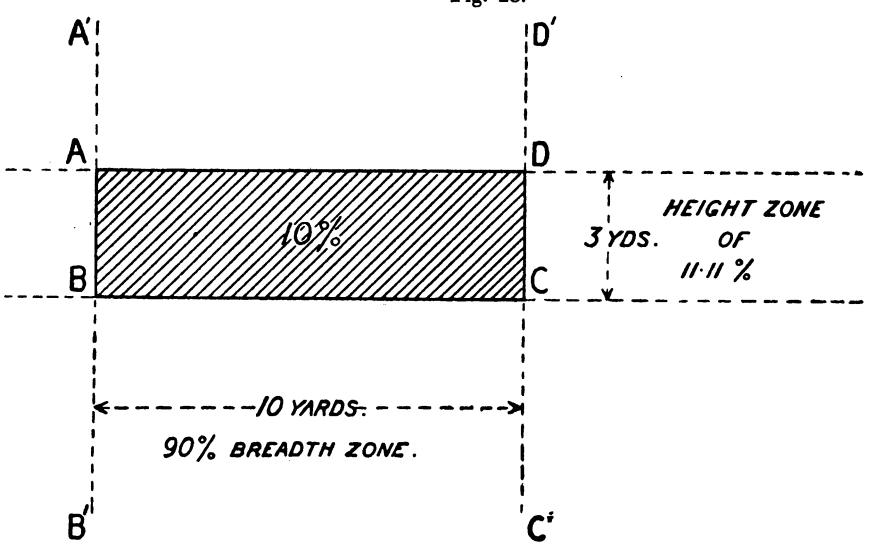
Therefore a greater percentage of hits will be made in Case (2).

The range tables' 50 % zones must usually be considered as guides to the probable number of hits, for, in the first place, they sometimes depend upon five rounds only, and, in the second place, the conditions of practice often differ materially from those obtaining during the trials at Shoeburyness. The best plan for determining the probable percentage of hits is to work back step by step from the number of hits actually obtained at practice. An instance of this is given.

EXAMPLE 5.

Firing at a target 10 yards broad and 3 yards high, a battery made 10 % of hits and 10 % of lateral misses. What percentage of hits may be expected on a target 100 yards broad and 9 yards high, provided the practice is carried out by the same battery under the same conditions?

Fig. 28.



Digitized by Google

Since there are 10 °/₀ of lateral misses, therefore there must be 90 °/₀ of hits on the zone A'B'C'D', this is the breadth zone of 10 yards.

∴ the breadth of the 10 yards of target will catch 90 °/₀ of the hits.

Let

Q °/₀ hits fall on target ABCD,

q_1 °/₀ „ „ breadth zone AD,

q_2 °/₀ „ „ height zone CD,

$$\therefore Q = q_1 q_2.$$

But

$Q = 10$ °/₀ from the question,

$q_1 = 90$ °/₀.

$$\therefore q_2 = \tfrac{1}{9}\tfrac{0}{0} \text{ of } 100 \text{ °/₀} = 11{\cdot}11 \text{ °/₀},$$

i.e., a height 3 yards is an 11·11 °/₀ zone.

Since

10 yards breadth is a 90 °/₀ zone,

$$\therefore \frac{10}{2{\cdot}44} \text{ „ „ „ } 50 \text{ °/₀ zone},$$

$$4 \times \frac{10}{2{\cdot}44} \text{ „ „ „ } 100 \text{ °/₀ zone}.$$

Since $\frac{40}{2{\cdot}44}$ is less than 100 yards, therefore a 100 yards breadth of target will certainly catch 100 °/₀ hits.

Again,

3 yards height is an 11·11 °/₀ zone,

$$\therefore \frac{3}{0{\cdot}202} \text{ „ „ „ } 50 \text{ °/₀ zone} = P.$$

The height, target being 9 yards high, = T.

$$\frac{T}{P} = \frac{9}{\left(\frac{3}{0{\cdot}202}\right)} = 0{\cdot}606,$$

which corresponds to 31·6 °/₀, *i.e.*, a target 9 yards high will catch 31·6, hence the target 100 yards wide and 9 yards high will have 100 °/₀ of 31·6 °/₀, *i.e.*, 31·6 °/₀ of hits.

Example 6.

Firing a 6-inch B.L. Mark III at a horizontal target 60 yards long in range and of unlimited breadth, at a range of 2000 yards where the 50 °/₀ zone for range was 40 yards long, it was found that only 25 °/₀ of hits was made, instead of the full number of 68·5 °/₀. Show by trial that the point of mean impact was about 50 yards from the centre of the target.

Given M.V. = 1327 f/s.

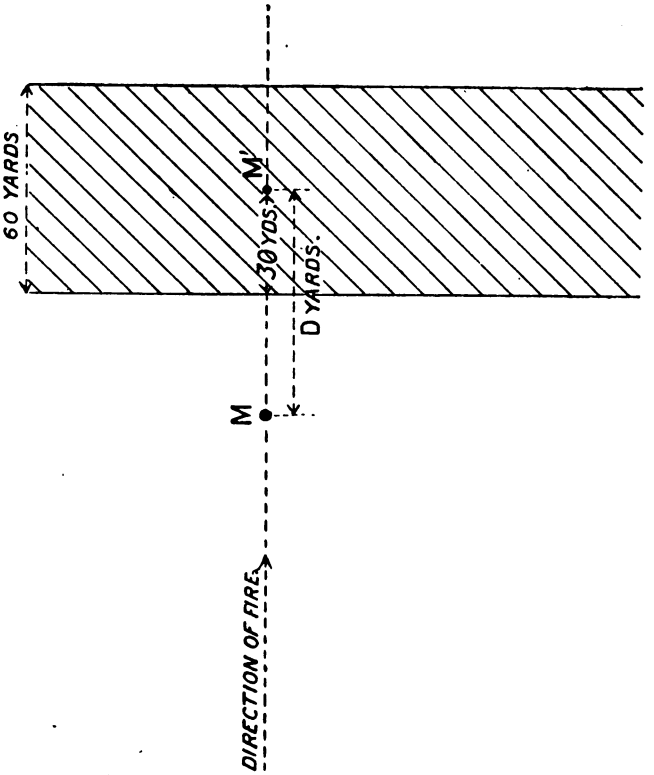
Five minutes extra elevation makes a difference of 38 yards at 2000 yards range.

What change of elevation did the gun require ?

The shaded portion represents the target 60 yards long.

Digitized by Google

Fig. 29.



Since

P, the 50 °/₀ length zone, is 40 yards,

T „ target, is 60 yards.

and

$$\frac{T}{P} = \frac{60}{40} = 1{\cdot}5.$$

We see at once from Table A that if the mean point really were at M′, then 68·5 °/₀ of shots would have fallen on the target zone. But since only 25 °/₀ of hits were made, the mean point of impact M cannot be at M′; suppose it to be as shown, then it is required to find the displacement MM′.

Let MM′ = D yards.

Then we have for length zone

T = 60 yards,

D is unknown,

P = 40,

and therefore the percentage q of shots that will fall on the target is

$$q = \tfrac{1}{2}\left[f\left(\frac{T + 2D}{P}\right) + f\left(\frac{T - 2D}{P}\right)\right],$$

and q we know to be equal to 25 °/₀,

Digitized by Google

$$\therefore\ 50\ \%_o = f\left(\frac{T + 2D}{P}\right) + f\left(\frac{T - 2D}{P}\right)$$

$$= f\left(\frac{60 + 2D}{40}\right) + f\left(\frac{60 - 2D}{40}\right).$$

By trial we see that D is > 0 but $\not> 50$, and that when D = 50 the equation is satisfied at once, because then

$$f\left(\frac{60 + 100}{40}\right) + f\left(\frac{60 - 100}{40}\right)$$

$$= f(4) - f(1) = 100\ \%_o - 50\ \%_o = 50\ \%_o.$$

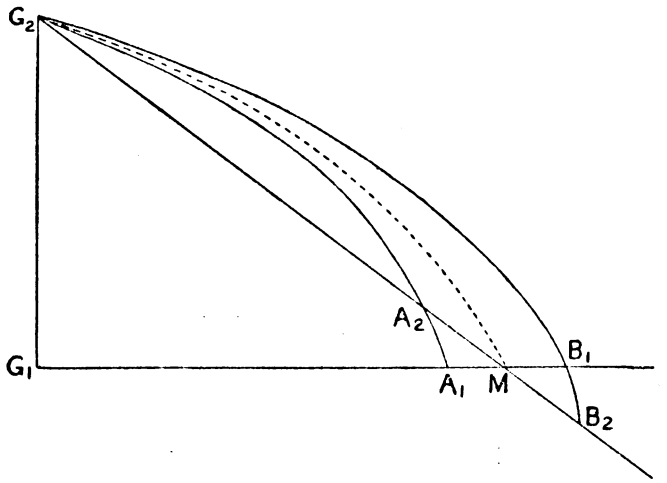
If at 2000 yards 5 minutes extra elevation gives 38 yards, then $\left(\frac{50}{38} \times 5\right)$ minutes are necessary for 50 yards, *i.e.*, about 6 minutes.

EXAMPLE 7.

Given that the 50%$_o$ zones for length of the 6-inch B.L. and of the 9-inch R.M.L. guns, at a range of 2000 yards, are 18 yards and 23 yards, determine the height of site which will put the 9-inch gun on equal terms with the 6-inch gun for accuracy of shooting at a sea-target, the 6-inch gun being at sea-level.

(The angle of descent at 2000 yards of the 9-inch gun is given in the Range Table as 3° 20′.)

Fig. 30.



The figure is merely to help the explanation, it is not to any scale, and heights and angles are greatly exaggerated to enable these to be clearly shown.

The two guns are at G_1, G_2, and M is the mean point of impact; the height G_1G_2 or H feet is to be found.

$$A_1B_1 = 18 \text{ yards}, \quad A_2B_2 = 23 \text{ yards}.$$

The angle of descent β is $= \angle B_1B_2M = \angle MA_2A_1$, also it is clear that all the shots from G_2 (the 9-inch gun) which fall on A_2B_2 will be caught on the horizontal zone A_1B_1.

Digitized by Google

Let S be the angular depression in minutes, so that

$$S' = \angle A_2MA_1 = \angle B_2MB_1.$$

Then from the triangle A_1A_2M,

$$\frac{A_2M}{A_1M} = \frac{\sin A_2A_1M}{\sin A_1A_2M} = \frac{\sin(\beta + s)}{\sin \beta} = \frac{\beta + s}{\beta}.$$

But

$$\frac{2\,3}{1\,8} = \frac{A_2B_2}{A_1B_1} = \frac{A_2M}{A_1M}, \quad \therefore \frac{2\,3}{1\,8} = \frac{\beta + s}{\beta}, \quad \frac{5}{18} = \frac{s'}{200'},$$

from page 5,

$$s' = 1146\frac{h}{R}, \quad \text{hence } h = 97 \text{ feet.}$$

There are two targets, one of which is 6 feet wide and the other 12 feet wide, both are of the same height. The mean point of impact is in the line joining the centres of the targets and is 3 feet from the 6-foot wide target; what distance must the 12-foot target be from the mean point of impact, so that the percentage of hits may be the same on either target?

Given that the width of the 50 °/₀ breadth zone is 6 feet.

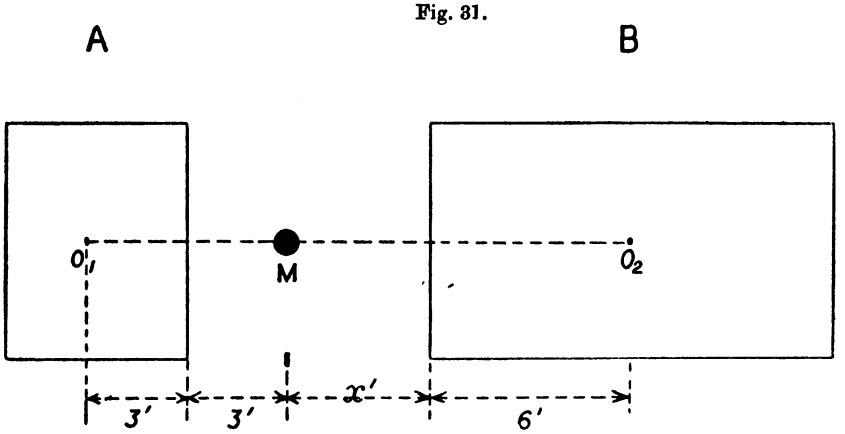
The height or vertical errors can be neglected, since they bear the same proportion for either target.

Target A is 6 feet wide; Target B is 12 feet wide.

Let M be the mean point of impact, so that

$$O_1M = 3 + 3 = 6 \text{ feet.}$$

Fig. 31.



Percentage on A is

$$q_1 = \tfrac{1}{2}\left[f\left(\frac{T_1 + 2D_1}{P}\right) + f\left(\frac{T_1 - 2D_1}{P}\right)\right],$$

where

$$T_1 = 6 \text{ feet},$$
$$D_1 = 6 \text{ ,,}$$
$$P = 6 \text{ ,,}$$
$$\therefore q_1 = \tfrac{1}{2}[f(3) - f(1)]$$
$$= \tfrac{1}{2}(96 - 50)\ ^{\circ}/_{\circ}$$
$$= 23\ ^{\circ}/_{\circ}.$$

Digitized by Google

Percentage on B is

$$q_2 = \tfrac{1}{2}\left[f\left(\frac{T_2 + 2D_2}{P}\right) + f\left(\frac{T_2 - 2D_2}{P}\right)\right],$$

where

$$T_2 = 12 \text{ feet},$$

$$D_2 = (x + 6) \text{ feet},$$

$$P = 6 \text{ feet},$$

$$\therefore q_2 = \tfrac{1}{2}\left[f\left(4 + \frac{x}{3}\right) - f\left(\frac{x}{3}\right)\right].$$

Since $4 + \frac{x}{3}$ is greater than 4, then obviously $f\left(4 + \frac{x}{3}\right)$ is 100 °/₀.

And now we are to have

$$q_1 = q_2,$$

so that

$$46 \text{ °/}_0 = 100 \text{ °/}_0 - f\left(\frac{x}{3}\right)$$

$$f\left(\frac{x}{3}\right) = 54 \text{ °/}_0 = 1{\cdot}09$$

$$x = 3{\cdot}27 \text{ feet}.$$

Small Arm Ammunition.

With **small arms** very large numbers of rounds are manufactured, and a certain proportion are fired from standard rifles to test the accuracy of the ammunition; the powder or cordite is first tested separately.

A different method to artillery practice is followed in this case.

Rifles in rests are laid on large vertical targets at 500 yards, and series of 20 rounds are fired from each under as nearly as possible the same conditions. The vertical targets are 18 feet high, 12 feet wide, and are divided into smaller squares of 3 feet side, and these again into smaller ones 6 inches square. The point of impact of each round is noted and plotted on a diagram, see figs. 32, 33. The horizontal and vertical distance of each hit from some vertical and from some horizontal line is measured, the mean of each of these distances is then determined, and thus the point of mean impact; so far the plan resembles that previously described; but after this the plan adopted for small arms differs from the other: the *radial* distance of each hit from the point of mean impact is measured, and the mean of these radial distances gives the **figure of merit** furnished by the particular sample of ammunition employed.

Thus in Plate III the figure of merit of 20 rounds from a Lee-Enfield rifle on 18th July, 1905, was 5·25 inches, the ammunition on this occasion being special for Bisley.

In Plate IV the figure of merit of 20 rounds from a short Lee-Enfield rifle on 11th August, 1905, was 8·65 inches, the ammunition was some returned from South Africa and taken from loose and mixed lots.

CHAPTER IV.—INTERIOR BALLISTICS.

THE investigation of the relation connecting the *pressure*, *volume*, and *temperature* of the powder gas inside the bore of a gun, and of the *work* done by the expansion of the gas, constitutes the branch of artillery science called *Interior Ballistics*.

Under the same head may be considered the Measurement of Velocity, at any point of the bore as well as outside near the muzzle; also the theory of Recoil.

SECTION I.—WORK REALISED BY THE EXPANSION OF POWDER GAS.

Definition of Work.

Work is performed when a force, P pounds or tons, pushes a body through a distance s feet; it is measured by the product Ps, called foot-pounds or foot-tons, according as P is in pounds or in tons.

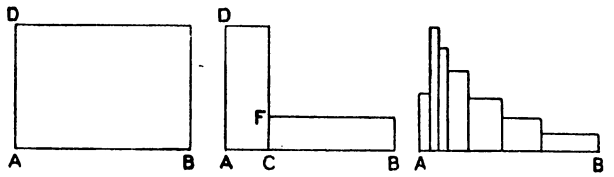
The **unit of work** (called the **foot-pound**) is the amount of work which is performed in raising a weight of 1 lb. through a distance of 1 foot vertical against gravity; but for artillery purposes the **foot-ton** is the unit generally employed, *i.e.*, the amount required to raise 1 ton 1 foot high; a foot-ton contains 2,240 foot-pounds.

Work done by a uniform force can be *represented graphically* by a rectangular area in which the height is proportional to the force P, and the base to the distance s through which the force acts.

Thus, if AD is proportional to P, and AB to s (fig. 1), the area DB will represent graphically the work done.

Suppose at some point C on AB (fig. 2) the pressure suddenly alters; if at C we erect a perpendicular and mark off on it CF, proportional to the new pressure, and complete the rectangle FB, the work will be represented by the sum of the two areas DC and FB.

Fig. 1. Fig. 2. Fig. 3.



If the pressure changes more than once we must take a greater number of rectangles (fig. 3), and the sum of the areas then represents graphically the work done by a pressure P which has suddenly changed in magnitude several times in acting on the body, over the distance AB.

Digitized by Google

Now, suppose the pressure to change in magnitude, but to do so *gradually*, as in fig. 4, in this case the number of rectangles becomes indefinitely increased, and the work done is represented by the area enclosed by a curved line (the locus of the corners of an indefinite number of rectangles).

In fig. 4 we have such a diagram where the pressure (as in the bore of a gun) begins from a moderate pressure, say 10 tons per square inch, soon rises to a high maximum, say 20 tons per square inch; then falls off at the muzzle to about two or three tons per square inch, and ceases soon after the projectile leaves the muzzle.

If a force has pushed a weight through a given distance, and has caused it to move at a certain velocity, work is *stored up*.

Suppose the work stored up was produced by the weight falling from a certain height h feet, under the acceleration of gravity g, until it had attained the same velocity v f/s.

The relation between v and h under these circumstances is given by the elementary dynamical formula—

$$\tfrac{1}{2}v^2 = gh$$

or

$$h = \frac{v^2}{2g}.$$

If the body weighs w lb., the work done must by definition be wh foot-pounds; substituting the value of h just obtained, this work is equal to

$$w\,\frac{v^2}{2g} \text{ ft-lbs., or } \frac{w}{2240}\cdot\frac{v^2}{2g} \text{ ft.-tons.}$$

With foot-second units we take $g = 32$, or more accurately,

$$g = 32{\cdot}19, \log g = 1{\cdot}5077.$$

This expression is a measure of the work contained in a moving body in terms of its weight and velocity; in this form it is called kinetic energy, or, shortly, **energy**.

It should be noticed that the amount of work increases as the *square* of the velocity; thus if the weight of the projectile is unchanged, and its velocity is doubled, the energy becomes quadrupled.

The energy in ft.-lbs. due to the rotation of a rifled projectile is expressed by

$$w\,\frac{(k\omega)^2}{2g},$$

in which k is the radius of gyration in feet, and ω is the angular velocity in radians per second, because

$$\Sigma\frac{w'v^2}{2g} = \Sigma\frac{w'\omega^2r^2}{2g} = \frac{\omega^2}{2g}\Sigma w'r^2 = \frac{\omega^2}{2g}\cdot wk^2,$$

where w' is a small element of weight w', at a distance r feet from the axis, and so moving with a velocity $v = \omega r$.

The *radius of gyration* of the projectile about its axis is defined to be that radius at which the whole weight of the shot may be supposed

Digitized by Google

concentrated in a ring, without altering its energy of rotation for given angular velocity ω.

If the pitch of the rifling is b feet, the shot will make a complete turn, an angle of 2π radians, when the shot advances b feet, the twist being uniform; so that if the shot is advancing with velocity v f/s, when the angular velocity is ω radians per second, such that

$$\frac{\omega}{2\pi} = \frac{v}{b};$$

and the energy of rotation is

$$\frac{4\pi^2 k^2}{b^2} w \frac{v^2}{2g} \text{ ft.-lbs.},$$

or $\frac{4\pi^2 k^2}{b^2}$ of the energy of translation or striking energy.

This is always small in proportion to the energy due to translation, and may generally be neglected in practice.

For example: For a solid cylindrical flat-ended shot $k^2 = \frac{1}{8}d^2$ and

$$\frac{4\pi^2 k^2}{b^2} = \frac{1}{2}\frac{\pi^2 d^2}{b^2} = \frac{\frac{1}{2}\pi^2}{n^2},$$

if the pitch $b = nd$ (n calibres).

Taking $\pi^2 = 10$, the factor becomes $\frac{5}{n^2}$.

Suppose $n = 25$, then

$$\frac{\text{the energy of rotation}}{\text{the energy translation}} = \frac{4\pi^2 k^2}{b^2} = \frac{5}{n^2} = \frac{5}{625} = \frac{8}{1000}$$

$$= 0{\cdot}008 \text{ (or } 0{\cdot}8 \text{ per cent.)}.$$

The work done by the powder pressure in the bore on the projectile must equal the energy contained in the projectile and the gun, less the work lost by friction.

Thus, if P is the mean total thrust in tons on the base of the projectile exerted over a length of bore s feet, we must have

$$Ps = \frac{w}{2240} \cdot \frac{V^2}{2g};$$

where V is the muzzle velocity of the projectile in feet per second, and w its weight in pounds, if the energy of rotation and of recoil and friction is neglected here.

The following examples will illustrate these definitions of work and energy:—

On firing a 6-inch B.L. Mark VII, the powder pressure acts on the base of the shell as it moves over a distance of 238 inches; the weight of the projectile is 100 lbs., and its M.V. is 2565 f/s. What must be the mean propelling force on the base of the shell?

Here

$$d = 6,\ w = 100;\ V = 2565;\ s = \frac{238}{12};\ g = 32{\cdot}19;$$

Digitized by Google

whence

$$P = w\frac{V^2}{2gs} = \frac{100}{2240}\frac{(2565)^2}{2g}\cdot\frac{12}{238}$$
$$= 230{\cdot}2 \text{ tons.}$$

Some additional thrust is also required to compress the driving-band into the grooves.

If the mean pressure p, in tons per square inch is required, we must divide the result just obtained by the area of the cross section of the bore in square inches.

$$\tfrac{1}{4}\pi d^2 = \tfrac{1}{4}\pi \times 36 = 9\pi = 28{\cdot}3,$$

and we obtain

$$p = \frac{P}{\frac{1}{4}\pi d^2} = 8{\cdot}14 \text{ tons/in.}^2$$

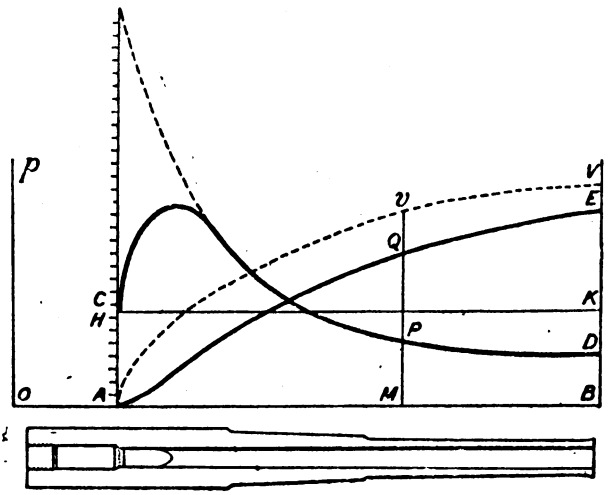
The maximum pressure, however, greatly exceeds this: it may reach 17 tons/in.^{2}.

A gun is a simple thermodynamic machine or heat engine, which does its work in a single stroke, and does not work in a series of cycles, as an ordinary steam engine.

The Maxim gun, however, tends to a resemblance with a steam engine in its power of sustained repeated action.

When a gun is fired, the shot is expelled by the pressure of the powder gas, and the relation between p, the pressure, and x, the volume of the gas, is represented graphically on what may be called the *indicator diagram* of the gun by means of a curve, CPD, in

Fig. 4.



which the ordinate MP represents the pressure p, and the abscissa OM represents the volume, x, each to an appropriate scale, when the base of the shot has advanced from A to M; the curve CPD starts from a point C, such that the ordinate AC represents the pressure when the shot begins to move (fig. 4), and the curve is generally called the "pressure-space curve."

Digitized by Google

Considering that the bore of the gun is cylindrical, the volume x grows at a uniform rate with the travel of the shot, so that we can take OM to represent volumes of expansion, provided the origin O is suitably placed to allow for the extra diameter usually given to the powder chamber OA.

The area AMPC then represents the work done by the powder (per unit area or square inch of cross section of the bore) when the base of the shot has advanced from A to M, the area ABDC representing the total work per unit area done by the powder as the base of the shot is leaving the muzzle B.

If OM represents inches of advance, and MP represents tons/in.^{2} (tons per square inch), then the area AMPC represents inch-tons of work per square inch of bore reducible to foot-tons by dividing by 12.

Suppose the shot weighs w lb., and that it acquires velocity v f/s at M, then equating the kinetic energy and the work done in ft.-tons,

$$\frac{w}{2240} \cdot \frac{v^2}{2g} = \frac{\text{area AMPC}}{12} \times \tfrac{1}{4}\pi d^2.$$

This supposes the bore is smooth; but if it is rifled with a pitch of b feet, the angular velocity at M is $\frac{2\pi v}{b}$ radians per second; so that if the radius of gyration of the shot about its axis is k feet, the kinetic energy is replaced by

$$\frac{w}{2240} \cdot \frac{v^2}{2g}\left(1 + \frac{4\pi^2 k^2}{b^2}\right) \text{ft.-tons};$$

and to allow for the friction of the bore, an empirical deduction is made from the pressure, represented in full by MP.

The curve of energy, AQE, is drawn such that its ordinate MQ represents to scale the work done by the powder, or the kinetic energy acquired by the shot, each proportional to the area AMPC; and thence the velocity curve AvV can be drawn, in which the ordinate Mv represents the velocity v, so that Mv is proportional to the square root of MQ

The pressure in the bore is determined experimentally by *crusher gauges*, described below; these are screwed into the bore at regular intervals in its length, as shown in the figure opposite, or else inserted in the projectile, or left loose behind the charge.

As a check upon the indications of the pressure gauges, Sir Andrew Noble inserts also a number of plugs, connected electrically with his chronoscope, and thereby determines experimentally the time occupied by the shot in its passage up the bore; thence the velocity at each point is inferred by calculation in exactly the same manner as the velocity outside from screen records, and the velocity curve can be drawn.

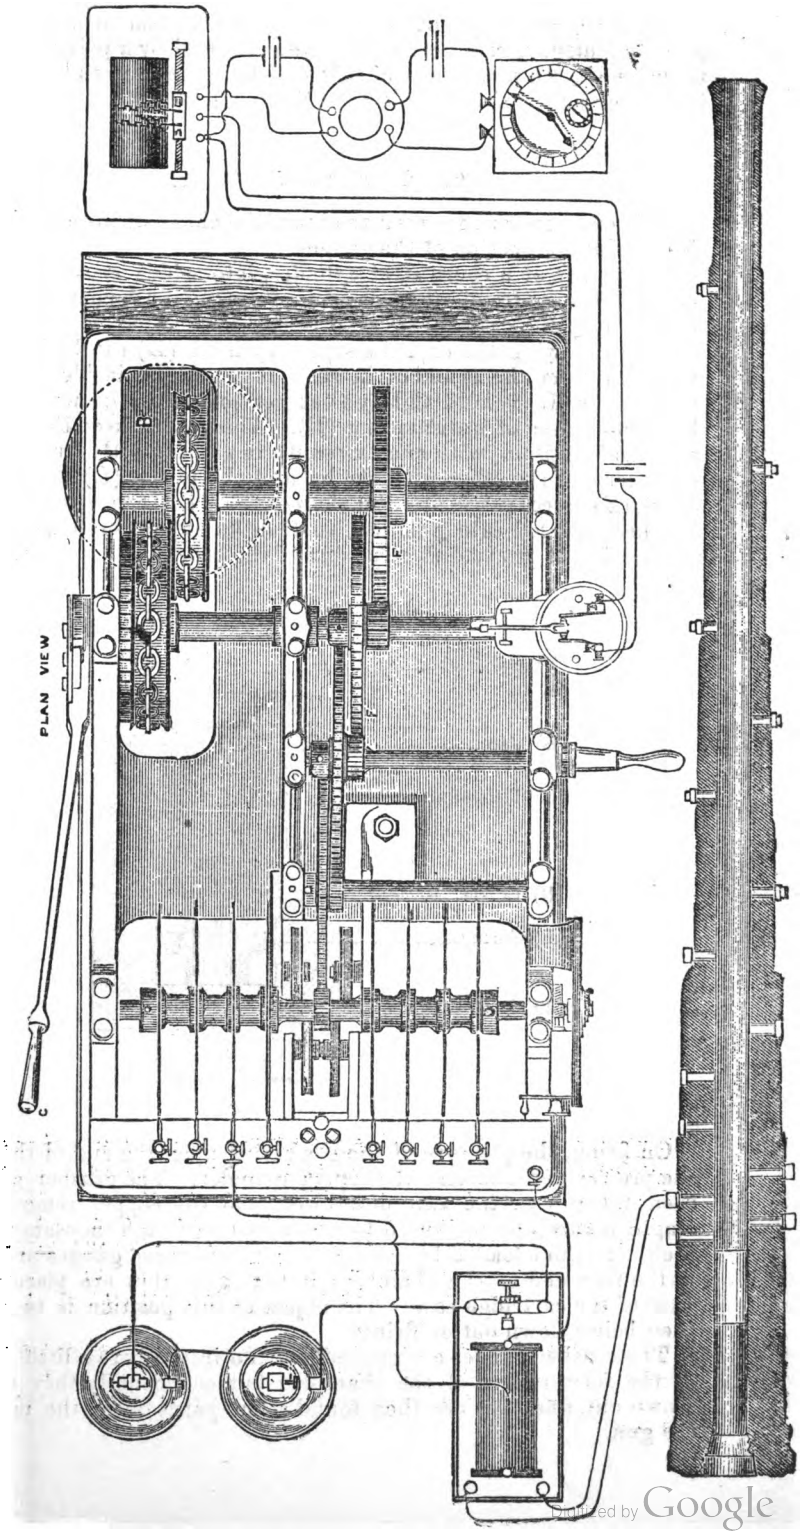
The energy curve is derived from this velocity curve, and thence the effective pressure accelerating the shot is determined; and these pressures are compared with the pressure recorded by the crusher gauges.

If the gun is free to recoil, there is a similar indicator diagram for the gun, representing the pressure or thrust on the base of the bore, or on the breech piece, at corresponding points of the length of the recoil.

Digitized by Google

Fig. 5.

CHRONOSCOPE.



Digitized by Google

The recoil can be measured at any instant by Colonel Sebert's velocimeter, consisting of a strip of smoked steel attached to the gun, on which, in recoiling, a wavy line is traced by a point on a fixed tuning fork, the period of which is known accurately, and this record is another independent check upon the previous methods.

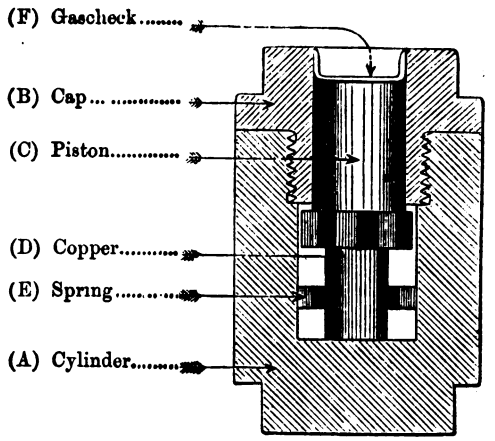
The Service Crusher Gauge.

This crusher gauge is used to obtain the chamber pressure in guns. Fig. 6 shows a section of the gauge.

It consists of a short steel cylinder, into which is screwed a cap, through the centre of which is accurately bored a hole one-sixth of a square inch in sectional area, and in this fits the piston.

By unscrewing the cap, the copper cylinder (D) can be inserted or removed from the chamber in the gauge; whilst inside the gauge, the copper (D) is held tightly (but not prevented from expanding) by a small piece of watch spring (E). This should keep the copper in a central position, with one extremity in contact with the end of the chamber and the other with the head of the piston (C); a small gas-check (F) of copper is fitted in the nozzle of the cap after the piston has been placed into position, so that its expansion prevents any penetration of gas into the chamber of the gauge.

Fig. 6. Scale full size.



On firing, the pressure of the gas acting upon the end of the piston compresses and shortens the copper cylinder. The crusher gauge is then taken out, the cap unscrewed, and the copper removed; its length is carefully measured by a micrometer to the thousandth of an inch. In guns loaded by hand, one or two of these gauges are placed at the rear end of the chamber; in Q.F. guns they are placed at the base of the cartridge case. The object of this position is to prevent their being blown out on firing.

The crusher gauges are generally found in the bore a little in front of the forward end of the chamber; but occasionally they may get blown out, and they are then found a few yards from the muzzle of the gun.

The following points should be attended to when using crusher gauges:—

(*a*) That the copper is placed fair in the gauge, and is not tilted.
(*b*) That the piston is pressed down on the copper, and does not return again from the compression of the air in the gauge.
(*c*) That the piston is free to move—not tight. It should be capable of being moved to and fro by the finger; a little Russian tallow applied to the piston, and also to the gas-check, facilitates the action and helps to keep the gas out.
(*d*) The gauge should be examined from time to time, to see that the piston hole is not conical instead of cylindrical, as it is found that the pressure has a tendency to make the piston hole smaller at the outer end, and, when this happens, the hole should be brought to size by careful lapping with emery.

The pressure in tons per square inch corresponding to any measured reduced length is then ascertained by reference to a table compiled originally from the compression of similar coppers in a statical pressing machine.

This table has been calculated to give the pressure in tons per square inch when a piston 0·461 inch in diameter (one-sixth of a square inch in sectional area) is used with a copper cylinder 0·5 inch long, and 0·326 inch in diameter (one-twelfth of a square inch sectional area).

Copper cannot always be obtained of the same uniform hardness as the sample for which the table for the crusher-gauge was drawn up. The half-inch cylinders are therefore subjected in a machine to pressure corresponding to 9, 12, and 15 tons per square inch, and those cylinders that after this treatment register a pressure differing from the tabular amount by more than 5 per cent. are rejected as unfit for use; for proof of cordite and other important experiments, the difference from the tabular amount should not exceed 1 per cent.

Thus no copper should be accepted that, having been pressed under 12 tons/in.^{2} in the machine, recorded by the table either less than 11·4 tons/in.^{2} or more than 12·6 tons/in.^{2}.

Coppers should be selected that have been pressed to about a ton/in.^{2} under the pressure expected in the gun.

For the coppers that fall between the limits of rejection a correction is made as shown in the two following examples:—

(1) A 12-ton copper before firing shows a length of 0·384 inch, and, after firing, a length of 0·348.

It will be seen from the table of corrective fractions that for a length of 0·384 the copper is $\frac{1}{60}$th soft, and a reduction of $\frac{1}{60}$th per ton must therefore be made from the pressure recorded after firing. From the length pressure table we see that a length of 0·348 corresponds to a pressure of 14·9 tons in.^{2}, then 14·9 tons less $\frac{1}{60}$th of 14·9 gives the true pressure, viz., 14·7 tons in.^{2} (neglecting hundredths).

(2) A 12-ton copper before firing shows a length of 0·390 inch, and after firing 0·348 inch. In this case the copper is $\frac{1}{40}$ hard, and the true pressure becomes 15·2 tons in.^{2}.

The results of chronoscope experiments with the 6-inch gun are shown diagrammatically in figs. 7 and 8 (pressure-space curves), and in figs. 9 and 10 (velocity-space curves).

Gravimetric Density.

The gravimetric density of the charge in the chamber of a gun is the ratio of its weight to the weight of that volume of water which would fill the space behind the projectile in the gun; or it is the specific gravity of the gaseous products of combustion which fill the chamber when the charge (cordite) is fired.

When a charge of P lbs. is placed in a chamber of C cubic inches, we have

$$\frac{C}{P} \text{ cubic inches to each lb. of charge,}$$

so that

$$1 \text{ cubic inch weighs } \frac{P}{C} \text{ lb.}$$

Also

27·73 cubic inches of water at 62° F. weigh 1 lb.

$$\therefore \text{ 1 cubic inch of water weighs } \frac{1}{27{\cdot}73} \text{ lb.}$$

Gravimetric density (G.D.) or specific gravity of charge

$$= \frac{\text{weight of 1 cubic inch of charge}}{\text{weight of 1 cubic inch of water}}$$

$$= \frac{\frac{P}{C}}{\frac{1}{27{\cdot}73}} = 27{\cdot}73\,\frac{P}{C}$$

$$\therefore \text{ G.D.} = 27{\cdot}73\,\frac{P}{C}.$$

The specific volume (S.V.) of a charge is the number of cubic inches allotted to one pound of the charge, so that

$$\text{S.V.} = \frac{C}{P} \text{ ins.}^3\text{/lb.}$$

With metric units, if P is in grammes and C in cubic centimetres,

$$\text{G.D.} = \frac{P}{C}$$

$$\text{S.V.} = \frac{C}{P} \text{ cm.}^3\text{/gramme,}$$

and no factor 27·73 is required, because 1 cubic centimetre of water weighs 1 gramme.

As an example, in the 6-inch B.L. Mark VII., the capacity of the chamber is 1715 cubic inches, and the charge is 20 lbs. cordite Mark I.

$$\text{S.V.} = \frac{1715}{20} = 85{\cdot}75,$$

$$\text{G.D.} = 27{\cdot}73 \times \frac{20}{1715} = 0{\cdot}3233,$$

Digitized by Google

and so the charge for this gun is expressed as 20 lbs. cordite Mark I,

$$\text{density } \frac{85{\cdot}75}{0{\cdot}323}$$

In the same gun, if the charge is 23 lbs. of cordite M.D., then the

$$\text{S.V.} = 74{\cdot}56 \text{ ins.}^3/\text{lb.},$$

$$\text{G.D.} = 0{\cdot}372,$$

so that

$$\text{density is expressed as } \frac{74{\cdot}56}{0{\cdot}372}.$$

Gravimetric volume (G.V.) is the reciprocal of gravimetric density, so that

$$\text{G.V.} = \frac{C}{27{\cdot}73P} \left(= \frac{C}{P} \text{ in the metric system}\right)$$

$$= \frac{\text{volume of the gas}}{\text{volume of an equal weight of water}}.$$

Explosion Vessel.

An explosion vessel consists of a chamber with very strong walls of mild steel; in this, a charge of explosive is placed and fired electrically; the pressure is noted by means of a crusher gauge enclosed, and the permanent gas can be drawn off and examined. (Experiments of Sir Andrew Noble and Sir Frederick Abel, Phil. Trans. 1875, 1880, 1892, 1894.)

In figs. 11 and 12 is a mild steel vessel of great strength, carefully tempered in oil, in the chamber of which (B) the charge to be exploded is placed. The chamber is capable of holding 1 kg. of powder, or 1 litre of water.

The main orifice of the chamber is closed by a screwed plug (C), called the firing plug, which is fitted and ground into its place with great exactness.

Fig. 11.

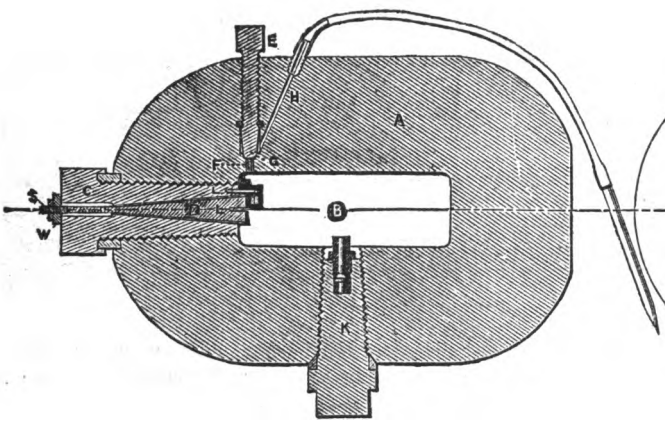

Fig. 12.

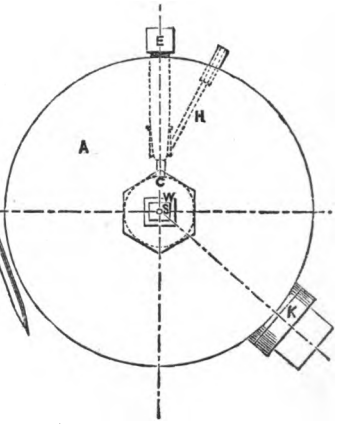


In the firing plug itself is a conical hole, which is stopped by the plug D, also ground into its place with great accuracy. As the firing plug is generally placed on the top of the cylinder, and as, before

Digitized by Google

firing, the conical plug would drop into the chamber if not held, it is retained in position by means of the set-screw S, between which and the cylinder a small washer (W) of ebonite is placed. After firing the cone is, of course, firmly held, and the only effect of internal pressure is more completely to seal the aperture. At E is the arrangement for letting the gases escape; the small hole (F) communicates with the chamber where the powder is fired, and perfect tightness is secured by means of the mitred surface (G).

When it is wished to let the gases escape, the screw (E) is slightly withdrawn, and the gas passes into the passage H.

At K is placed the crusher apparatus for determining the pressure at the moment of explosion.

When it is desired to explode a charge, the crusher apparatus, after due preparation, is first carefully screwed into its place, and the hole (F) closed. The cone in the firing plug is covered with the finest tissue paper, to act as an insulator.

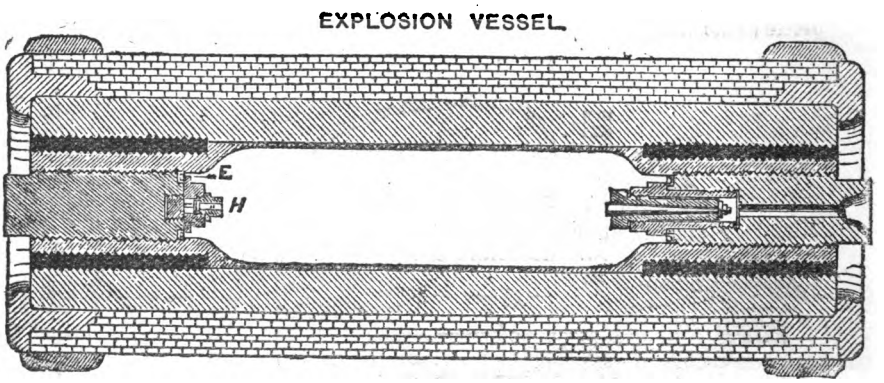
The two wires (L, L), one in the insulated cone, the other in the cylinder, are connected by a very fine platinum wire passing through a small glass tube filled with mealed powder. Upon completing connection with a Daniell's battery the charge is fired.

The only audible indication of the explosion is a slight click; but frequently, upon approaching the nose to the apparatus, a faint smell of sulphuretted hydrogen is perceptible.

Great care was necessary in exploding the powder in this chamber, and any looseness of screws at once gave an exit to the gas, which washed away the metal of the threads in its rapid rush. When such a state of things occurred, the metal had apparently been fused.

Fig. 13 shows an explosion vessel, which is even stronger made, being wound with steel wire.

Fig. 13.



The maximum pressure only is recorded by the crusher gauge, but explosion vessels of new pattern are arranged for recording the time rate at which the pressure rises to the maximum.

The volume of the chamber of the explosion vessel is known accurately, and the gravimetric density of a charge (P lbs.) to be exploded is given by

$$G.D. = 27{\cdot}73\,\frac{P}{C}.$$

Thus, if the chamber capacity is 27·73 cubic inches, then a charge of 1 lb. would have a density of loading equal to 1, and a charge of 4 ozs. a density equal to $27{\cdot}73 \frac{0{\cdot}25}{27{\cdot}73} = 0{\cdot}25$, and so on.

The maximum pressure recorded depends upon the density of loading of each charge.

The latest and very exhaustive experiments on explosives are those carried out by Sir Andrew Noble, K.C.B., F.R.S., and the following information is taken from his paper in the Philosophical Transactions of the Royal Society of London, Series A, vol. 205, pp. 201–236, 1905 and 1906.

TABLE of Pressure in Explosion Vessel.

G.D. of charge exploded.	Pressure in tons per square inch.	
	Cordite Mark I.	Cordite M.D.
0·05	2·9	2·7
0·10	7·8	6·9
0·15	11·49	10·2
0·20	17·2	15·2
0·25	21·08	20·7
0·30	30·5	27·62
0·40	41·4	38·1
0·50	52·9	43·22

The curve diagrams (fig. 14) show the rate of cooling of the gases in the explosion vessel, that is the rate at which they communicate the heat accompanying the explosion to the walls of the vessel in which the explosion takes place.

By means of Sir A. Noble's diagram giving the relationship between density of charge in an explosion vessel and the recorded pressure, the work capable of being done by one pound of cordite Mark I or M.D. in foot-tons, as the volume changes from unity to any other volume can be obtained; the unit volume is 27·73 cubic inches.

5·0	368·8	27·0	644·5		

From fig. 15, the curve giving the relationship between the pressure and the gravimetric volume can be deduced, and by the quadrature of this curve, the work E in foot tons realised by the expansion of 1 lb. of cordite M.D. gas from one gravimetric volume to another can be obtained, on the assumption that the pressure in the closed vessel is the same as when the gas is expanded in the bore of the gun. By this method the above table of work done by 1 lb. of cordite M.D. is obtained.

Suppose the average pressure is p-tons/in.^{2} at an average G.V. v, then while the G.V. changes by Δv from $v - \frac{1}{2}\Delta v$ to $v + \frac{1}{2}\Delta v$, a change of volume of 27·73 Δv in.^{3}, the work done is 27·73 $p\Delta v$ in.-tons, or in ft.-tons

$$\Delta E = 2{\cdot}31\, p\Delta v.$$

A summation of all the values of ΔE, as is done in the Ballistic Tables, gives E.

Conversely, from a table of E in terms of v, the value of p can be found from the formula

$$p = \frac{1}{2{\cdot}31} \cdot \frac{\Delta E}{\Delta v}.$$

In calculating the muzzle energy and velocity to be expected from a given charge of P lbs. of the cordite in expanding from the volume C in.^{3} of the chamber to the total volume B in.^{3} of the bore, including

Digitized by Google

the chamber, the initial and final gravimetric volumes (G.V.) denoted by v_0 and v_1 are calculated from

$$v_0 = \frac{C}{27 \cdot 73P}, \quad v_1 = \frac{B}{27 \cdot 73P},$$

and then the difference

$$E(v_1) - E(v_0)$$

of the corresponding values of E, multiplied by P, the charge in lb., gives the maximum realisable work in ft.-tons.

In practice, a factor f is employed to obtain the actual net realised work stored up in the shot on leaving the muzzle.

SECTION II.—MEASUREMENT OF VELOCITY.

For ordinary purposes, such as proving cordite, by finding what velocity a given charge will impart to a given projectile in a gun, the **Boulengé chronograph** is employed.

The original pattern of Le Boulengé was subsequently improved upon by Captain Bréger, of the French marine artillery, with a view to reduce the mechanical and electrical sources of error.

The general principle of its action remaining as before, the Boulengé-Bréger instrument has been improved recently by Major H. C. L. Holden, R.A.; besides alterations in the instrument itself, all the regulating appliances are now grouped together on a board; better forms of rheostats, and a much more accurate disjunctor have been fitted, and a commutator has been introduced, the use of which will be explained later on.

Fig. 2 shows the instrument as improved by Major Holden; fig. 3, is the new disjunctor; and fig. 4 is a diagram of the connections on the switch or instrument board.

The whole arrangement consists of two separate parts:—

(1.) That on the proof ground consisting of gun position, butt, and the mechanical arrangement whereby the electrical circuits are broken by the projectile, viz., screens and the system of electrical circuits (*see* the right-hand side of fig. 1).

(2.) The instrument room containing the chronograph, batteries, regulating and testing appliances, also electric circuits in connection with those on the proof ground (as shown on the left).

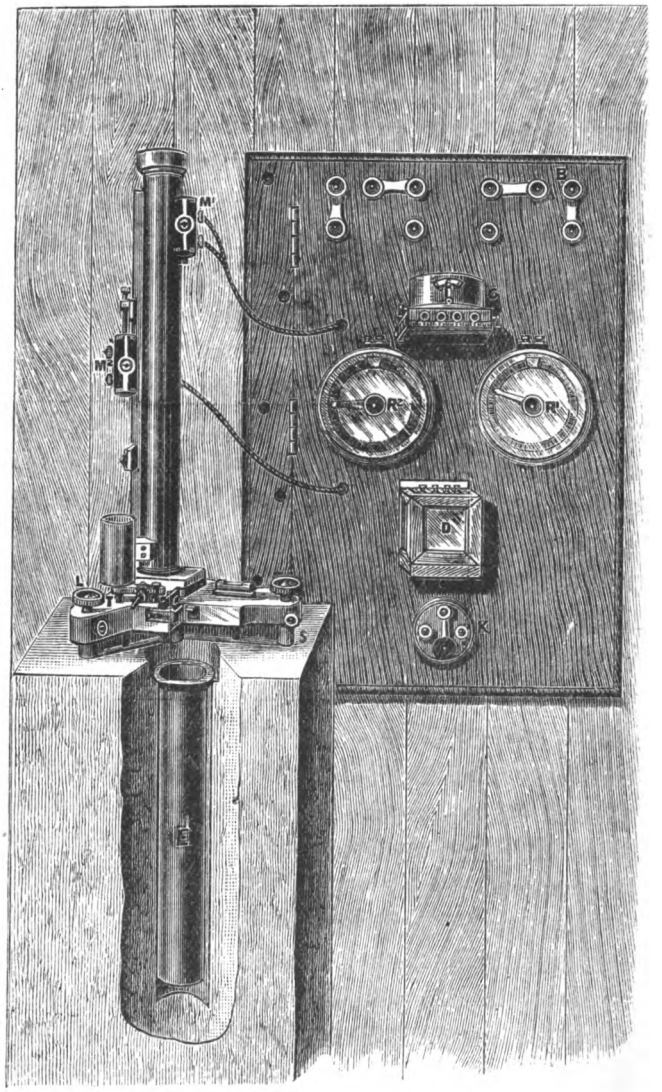
Fig. 1.

Digitized by Google

From the instrument room, about 300 yards distant, a number of copper wires insulated with gutta-percha are severally connected to the instruments at one end, and on the proof ground are led up into strong cast-iron boxes H and L (fig. 1) above the surface of the ground and fixed to terminals on ebonite bars in the boxes. The

Fig. 2.



screens themselves consist of upright oblong wooden frames, about 8 feet high by 4 feet wide between the sides, and they are combined in sets of two or three on one stand, so that the records for two or three instruments may be obtained simultaneously and independently of each other.

Digitized by Google

The frames are provided on their two vertical faces with a series of insulated pegs, so that a wire can be stretched continuously backwards and forwards across the frame from top to bottom of it, for the shot to cut, the distance between each return of wire being always less than the diameter of the shot fired.

One end of the wire wound on the screen is attached to the outgoing wire from the terminal box, and the other end to the return wire. The general arrangement will be seen by fig. 1 ; only, for the sake of clearness, the wires from the instruments to the terminal boxes are shown in the air instead of underground.

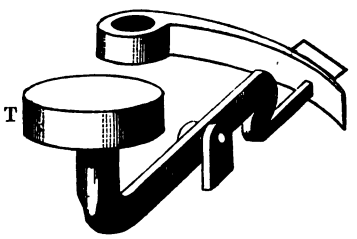
The screens slide sideways on rails fixed accurately 180 feet apart. The distance of the first screen from the muzzle of the gun being from 190 to 150 feet with guns of large calibre, though a much smaller distance is ample for light guns, on account of the disturbance due to their muzzle blast being less.

In the instrument room, the chronograph (fig. 2) consists of a substantial vertical brass pillar which supports two electro-magnets, M^1 on its right-hand side, and M^2 on its left. Of these two magnets, M^1 is fixed permanently, whilst M^2 can be moved up and down the pillar by means of quick and slow motions, and can be clamped temporarily in any position. The pillar stands on a triangular base which can be levelled by means of the levelling screws and two spirit levels at right angles to each other.

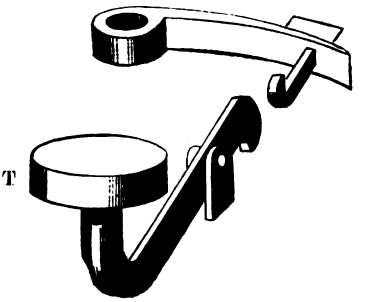
The concrete pillar should not touch the floor or walls of the building in which it is built, as if it did so, it would be liable to participate in the vibration.

The electro-magnets, M^1 and M^2, are exactly similar, mechanically, electrically, and magnetically, and they are capable of supporting from their conical-ended projecting iron cores two rods weighing 14 ounces each. The one that is supported by the magnet M^1 being some 22 inches long, and the other 5 inches long. They are both provided with bobs at their lower end to keep the centre of gravity as low as possible.

Sketch of Trigger.



(*a*) Cocked.



(*b*) Spring released so that the knife on it may mark the chronometer rod.

The longer, or "chronometer rod," when released from the magnet M_1 falls into a tube; but the shorter rod or "registrar," supported by the magnet M^2 falls through a guard tube on to a trigger table, T, which is thereupon pressed down, releasing a spring which has affixed to it a cutting edge, and is situate on the right-hand side of the base of the pillar. This spring, carrying the cutting edge, moves

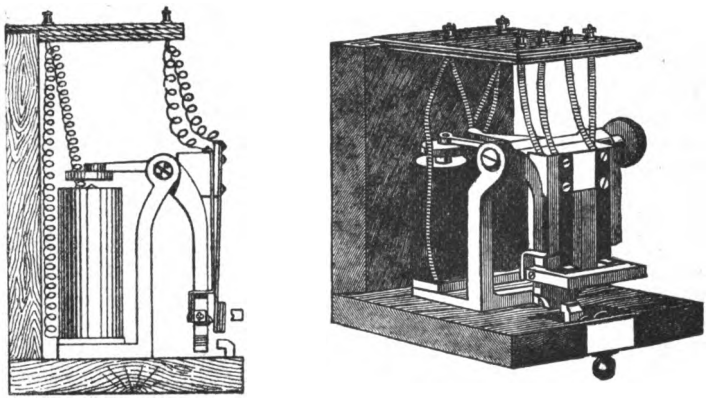
Digitized by Google

to the right in a horizontal plane, and when it comes in contact with the falling chronometer rod makes a mark thereon which constitutes the record.

1. *The Rheostats* R^1, R^2, *or Adjustable Resistances.*—These are of circular form, and so arranged that, by moving the radial arm, resistance can be interposed or taken out of the circuit without breaking it. One rheostat is included in the circuit of each electro-magnet, and serves to regulate the current through the coil.

2. *The Disjunctor D.*—This is shown, with the cover removed, in fig. 3. It consists of an electro-magnet, the armature of which forms one end of a swinging ⅂-shaped frame, and is situate horizontally

Fig. 3.



above the poles of the magnet. The vertical, or other leg of the swinging frame, carries two flat steel springs of equal strength, separately insulated, and loaded at their lower extremities by brass weights, which in the position of rest make contact through iridium contact points with two fixed contacts also attached to the frame. A guardpiece extends from one side of the frame to the other, and prevents the springs moving more than a certain distance away from the contacts.

3. *The Commutator C.*—The commutator comes next under our consideration. This is a most important accessory, and fulfils two functions.

(1.) The cutting off of the current from the instrument when not actually in use.

(2.) The changing of the two magnet circuits through the disjunctor above described, so that either spring or contact may be in the circuit of either magnet, or *vice versâ*, the object of this being to check and be able to correct for any small error in the working of the disjunctor, such as dust in the contacts, unevenness in the power of the springs, &c., &c.

It consists of a horizontal board, with 12 holes in 3 rows of 4 each. Each of these holes contains mercury, and is in connection with a binding screw on the outside of the case. The four front screws are in connection with the central row of holes, and these are thus in direct connection with the two magnet circuits.

An insulated rocking arm, carrying four suitably-shaped pieces of copper, also insulated from each other, is placed immediately above

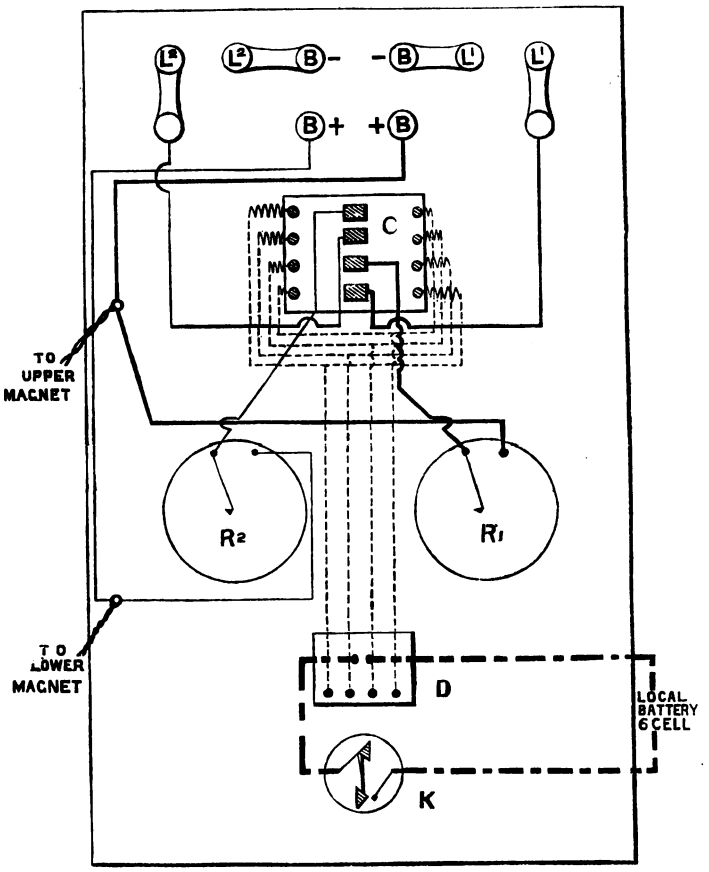
Digitized by Google

the central line of mercury contacts; and by moving this to the right or left by means of the lever arm and indicator outside the case, the central holes can be connected to those on either side, or by placing the lever in the centre disconnected from either.

To the terminals, L^1 L^1, are connected the line wires to the screen nearest the gun—those of the farther screen being connected to the terminals L^2 L^2. By removing the connecting straps, which are seen between L^1 and $-B$ (the negative pole of the battery), and also between L^1 and the other terminal, the line wires are quite disconnected from the rest of the instrument, and can be tested. The condition of the battery can be tested by the application of a voltmeter to the terminals $-B$ and $+B$.

In fig. 4 the circuit of the chronometer (upper magnet) is shown

Fig. 4.—Diagram of connections.



by a thick line, and that of the registrar (lower magnet) by a thin line.

The rheostats having both been set to zero, or their position of lowest resistance, the chronometer or registrar rods are hung up to their respective magnets, each having had in the first instance a small tubular weight slipped over them. The resistance of each circuit is

Digitized by Google

then gradually increased, the chronometer circuit first, till the rods fall. The tubular weights having then been taken off, it will be found that the magnets are just capable of sustaining their respective rods, and that they are necessarily, from the mode of adjustment adopted, of exactly the same power.

Having suspended both the rods again, the disjunctor now comes into play; when the first screen is broken the chronometer rod begins to fall; but this action is not instantaneous, as on the cessation of the electric current in the coils, supposing the latter were instantaneous (which it cannot be), the magnetism of the core has still to fall below a certain strength before the chronometer rod is eased, and, therefore, there is delay. A similar delay occurs in the release of the registrar rod; but in this case there are yet other effects to be taken into account. In the first place, the registrar rod falls some distance before it strikes the trigger table; then the trigger table has to release the spring and knife, and the latter has to move a certain distance before coming into contact with the chronometer rod.

The function of the disjunctor is to remove all these time errors mechanically. On pressing the disjunctor key both circuits are broken instantaneously and both rods fall simultaneously. The height up the chronometer rod where the mark is made when this action is performed forms the means of eliminating the time errors.

For the sake of convenience, the position of the disjunction line on the chronometer rod is made a fixed one, viz., 4·345 inches above the zero, equivalent to a time of fall of 0·15 of a second, from

$$h = 6g\ (0{\cdot}15)^2 = 4{\cdot}345 \text{ inches } (g = 32{\cdot}19).$$

and the disjunction mark made by the instrument is adjusted by raising or lowering the registrar magnet M^2 on the pillar, so as to coincide exactly with the mark previously made on the rod.

To check the disjunctor, all that is necessary is to repeat the above operation with the lever of the commutator on the opposite side. If the disjunctor is in correct adjustment, the two marks will be at the same height on the chronometer rod; if they are not, the disjunctor requires adjusting.

The records taken are not actually on the chronometer rod itself, but on a silvered copper tube, which fits it sufficiently tight so as not to slip about on it, and so change its position. Around this copper tube, which lasts some 50 rounds or more, a fine line is made at a height of 4·345 inches above the zero, by means of a special instrument for the purpose.

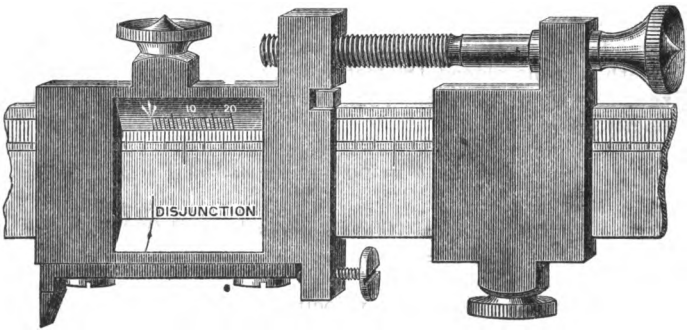
The chronograph instrument having now been adjusted, and the disjunctor line, as it is called, established correctly, the gun is fired, the projectile passes through the screens, and the chronometer and registrar rods fall one after the other. The chronometer rod having been taken out of the fall tube and examined, it will be found that the mark on the rod is made some distance above the disjunctor line, and the distance of this mark above zero is a measure of the time the projectile has taken to pass between the screens plus the time the registrar takes to fall and the knife takes to act.

The distance is measured carefully by means of a scale (see fig. 5) which can be applied to the rod. It consists of a metal bar with a hinged end carrying a conical plug which fits into a socket prepared for it at the lower end of the chronometer rod, and having a zero point coinciding exactly with that of the instrument with which it is

Digitized by Google

used; *i.e.*, with the point on the chronometer rod opposite to the knife when the rod is hung up. On the scale are two slides, either of which can be clamped with it. One is fitted with a micrometer screw, by which the other can be moved short distances for final adjustment of reading.

Fig. 5.



The scale is graduated on its upper edge in inches, and can be read to thousandths by means of a vernier; then, by measuring the distance of the mark up the rod from the zero of the scale, the time taken by the shot in traversing the distance between the screens can be calculated as follows:—

Let

T = time in seconds between the commencement of fall of the chronometer rod and the mark made on the rod.

t = actual time in seconds of the shot between screens, so that T$-t$ is the disjunctor time;

h = distance in inches from zero to mark on chronometer rod;

g = acceleration of gravity;

then, since h is measured in inches,

$$\frac{h}{12} = \tfrac{1}{2} g\mathrm{T}^2,$$

so that

$$h = 6g\mathrm{T}^2, \quad \mathrm{T} = \sqrt{\frac{h}{6g}}, \; t = \mathrm{T} - 0{\cdot}15,$$

so that

$$v = \frac{l}{\sqrt{\frac{h}{6g}} - 0{\cdot}15},$$

and $v = \frac{l}{t}$ is the average velocity between the screens, l feet apart.

As an example, suppose the mark made on the chronometer rod was at 10·644 inches above the zero; putting $h = 10{\cdot}644$ in the above, gives T = 0·235 of a second.

Digitized by Google

Now from this we must deduct 0·15 of a second, the time taken for the registrar rod, trigger, and knife to act, giving $t = 0{\cdot}085$ of a second as the time taken to pass from one screen to the other.

Since the distance between the screens is 180 feet, the mean velocity must be

$$\frac{180}{0{\cdot}085} = 2118 \text{ f/s.}$$

This is assumed to be the *actual* velocity at the middle point, and when the resistance varies with the cube of the velocity it is absolutely true; even when the velocity is such that the resistance varies with some other power, the difference would not be practically appreciable when the distance considered is so short as 180 feet.

The lower edge of the scale being graduated in velocities, these can be read off directly, thus saving calculation.

With screens placed 180 feet apart, and time to the disjunctor mark fixed at 0·15 of a second, the formula required for graduating the velocity scale is

$$h = 6g\left(\frac{180}{v} + 0{\cdot}15\right)^2.$$

Putting $v = 1000$ f/s gives $h = 21{\cdot}033$ inches,
and $v = 2000$,, ,, $h = 11{\cdot}125$,,

And to obtain the muzzle velocity V use is made of the formula

$$S_V = S_s + \frac{s}{C}.$$

EXAMPLE 1—SERVICE PROJECTILE.

Suppose a 6-inch Q.F. gun to have been fired with a 100-lb. projectile of service pattern at 60 yards from the first screen, then the distance s from the muzzle to the middle point between the screens where the velocity $v = 2118$ f/s. has been observed by means of the chronograph, is $180 + 90 = 270$ feet, and $C = \frac{w}{d^2} = 2{\cdot}778$. Then

$$\begin{aligned} S_V &= S_{2118} + \frac{270}{2{\cdot}778} \\ &= 45616{\cdot}2 + 97{\cdot}2 \\ &= 45713{\cdot}4 \\ V &= 2148 \text{ f/s.} \end{aligned}$$

EXAMPLE 2—PROOF PROJECTILE.

At the Proof Butts projectiles of the same weight as the service projectile, but with flat heads, are used, and supposing the same middle point velocity v as in (1) to have been observed, but a proof shot to have been fired.

On account of the flat head, the factor $\kappa = 2$ is introduced, and

$$C = \frac{w}{\kappa d^2} = \frac{100}{2 \times 36} = 1{\cdot}389.$$

Digitized by Google

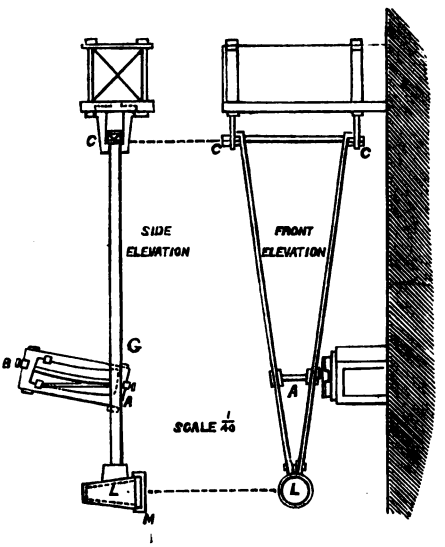
The coefficience of shape is commonly taken as $\kappa = 2$, but 1·8 is better for flat-headed projectiles (p. 29).

Now
$$\frac{S}{C} = 194{\cdot}4,$$
$$S_v = 45810{\cdot}6,$$
$$V = 2178 \text{ f/s}.$$

Before the adoption of electricity, the instrument employed for determining the velocity of shot was the ballistic pendulum, invented by Benjamin Robins in 1740.

This consists essentially of a large pendulum provided with an iron plate or a box filled with sand; the bullet strikes the plate and is shattered, or else the cannon ball is imbedded in the box of sand; and now the *diluted* velocity of the ball and pendulum causes the pendulum to swing back through a certain angle from which the striking velocity of the ball is inferred.

Fig. 6.—Musket Pendulum for Small Arms.



The musket pendulum is shown in fig. 6; and when, as here, the pendulum consists of a rigid framework, swinging bodily about the axis of suspension, it is important that the bullet should strike at or near a certain point called the centre of percussion, to minimise the shock on the axis of suspension.

The theoretical determination of this centre of percussion depends upon advanced dynamical considerations, although the position can be determined experimentally with great ease by noting the point where a plummet, suspended from the same axis, swings in the same period, and has no tendency to separate from the pendulum.

To avoid, however, all considerations of this centre of percussion, the rigid framework of the pendulum may be supposed replaced by five chains or cords, fig. 7, in accordance with Mr. Mallock's arrangement; and now if the box of sand or the block is struck by the ball

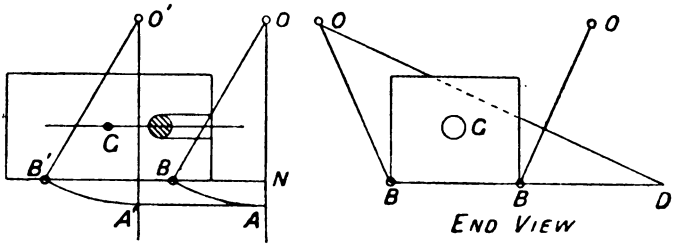
Digitized by Google

in a line passing horizontally through the centre of gravity or near it, the box will recoil, without rotation, through a certain height h feet, such that

$$h = \frac{U^2}{2g},$$

if the box and imbedded ball acquire a common velocity U f/s during the penetration.

FIG. 7.



If the ball, weighing w lbs., strikes with velocity V f/s, and is imbedded in the box weighing W lbs., then the velocity of the ball is *diluted* from V to U, such that

$$wV = (W + w)U,$$

in accordance with the principle of momentum; and thence

$$V = \frac{W + w}{w}\sqrt{(2gh)}.$$

If a point A on the box in recoiling draws out a tape to a length c, the chord of the circular arc AB described by the point A, and if the chains or cords are l feet long, so that the radius of the circular arc is l, then

$$c^2 = 2hl, \text{ because } AB^2 = \text{diameter} \times AN,$$

so that

$$V = \frac{W + w}{w}\sqrt{\frac{g}{l}} \cdot c = \left(\frac{W}{w} + 1\right)\frac{2\pi c}{T},$$

where

$$T = 2\pi\sqrt{\frac{l}{g}},$$

is the time in seconds of a double swing of the pendulum or V is proportional to c, so that this tape can be graduated uniformly for equal increments of velocity.

The striking energy of the ball, $\frac{wV^2}{2g}$ ft.-lbs., is reduced by the impact to

$$(W + w)\frac{U^2}{2g} = \frac{w^2}{W + w}\frac{V^2}{2g} \text{ ft.-lb.},$$

shared between the block and the ball; so that

$$\frac{Ww}{W + w}\frac{V^2}{2g} \text{ ft.-lb.}$$

of energy is dissipated or liberated by the blow.

Digitized by Google

If we suppose this energy is used up in penetrating the sand of the box to a distance a feet against an average resistance of R pounds, then

$$Ra = \frac{Ww}{W + w} \frac{V^2}{2g} = \tfrac{1}{2}(W + w) \frac{W}{w} \frac{c^2}{l} \text{ ft.-lb.},$$

whence R can be determined from an observation of a.

If the shot occupies t seconds in penetrating the sand, then Rt = momentum in second-pounds lost by shot or gained by box,

$$Rt = w \frac{V - U}{g} = W \frac{U}{g},$$

so that

$$t = \frac{w}{W + w} \cdot \frac{2a}{c} \sqrt{\frac{l}{g}} = \frac{w}{W + w} \cdot \frac{a}{\pi c} T$$

seconds, during which the box will have moved with average velocity $\frac{1}{2}U$, and therefore through a distance

$$\frac{aW}{W + w} \text{ feet},$$

this distance is so small in practice that we are justified in ignoring the curvature in the motion as assumed above.

Thus, for example, if W = 2,000 lbs., L = 8 feet, c = 6 feet, and w = 20 lbs., then we find v = 1,212 f/s; and if the penetration of the shot into the sand is 2 feet, a = 2; and then the mean resistance R = 227,250 lbs., and the time of penetration about 0·0033 or 1 ÷ 300 of a second, during which the box will have moved about 0·2376 inch, say, one-quarter of an inch.

Sometimes the gun or rifle is mounted on a pendulum, thence called the gun pendulum; in this case the pendulum measures the recoil, as felt on the shoulder when the rifle is fired; for this purpose the rifle can be suspended by two cords about 3 or 4 feet long; but the additional recoil, due to the blast of powder, prevents the gun pendulum from giving direct record of the muzzle velocity of the shot, but in the small arm trade the average allowance is known from other experiments and allowed for. The ballistic pendulum is of much practical use in the small arm trade.

A bullet-proof steel cuirass illustrates in a popular manner the principle of the ballistic pendulum.

If the cuirass weighed, for instance, 12 lbs., and was struck by a ½-oz. bullet with velocity 2,000 f/s, it would deliver a blow to the body as if let fall about 5 inches; this is about the same blow as is felt on the shoulder when firing the rifle, supposed of the same weight 12 lbs.

SECTION III.—RECOIL.

Consider a gun and carriage (either field, siege, or garrison) as one system. On firing, a resultant force acts along the axis of the piece and tends to produce two kinds of motion.

(1.) Motion of translation of the centre of gravity of the system.

(2.) Rotation round the centre of gravity of the system, or some fixed point, the spade for instance in a field gun.

Digitized by Google

We can consider these tendencies to motion separately.

(1.) The tendency to motion of the centre of gravity of the system produced by the act of firing can be resolved—

(*a*) Vertically, and
(*b*) parallel to the ground or platform.

The first of these tendencies causes a stress in the axletree, and eventually a downward thrust on the wheels of a field carriage.

A downward blow is also produced on the sides of a garrison carriage and on the slide. This downward blow is very destructive at high angles of elevation.

The component parallel to the ground is the more considerable and causes the motion of recoil, which is checked by various means.

This force produces a horizontal stress on the axletree of a field carriage. Tensile stays transfer the pull from near the middle to parts nearer to its points of support.

The form of axletree which appears to be best fitted to resist these various stresses is one which is circular in section, lightness being obtained by the uses of tubular steel.

In modern gun carriages the gun is allowed to recoil some distance in a cradle, the movement being controlled by a hydraulic buffer. This movement of the gun reduces very much the stress on the carriage, so that in a field gun the wheels need not move on the ground.

The equation connecting the velocity of recoiling parts and the velocity of shot at any time whilst the shot is in the bore will be shown. The actual recoil of the gun whilst the shot is in the bore is very small.

Fig. 1 represents the bore of a gun at the moment of firing and also the same gun t seconds after firing, while the shot is still in the bore.

G_0 is the centre of the powder chamber of length l'; x is the distance recoiled by the gun, and y is the space through which the shot has moved along the bore, all three being in the same units.

G_1 is the centre point of the volume occupied by the gas (assumed of uniform density) t seconds after firing, therefore

$$A_1G_1 = \tfrac{1}{2}(x + l' + y).$$

The space passed over in t seconds by the mid point of the charge is

$$\tfrac{1}{2}(x + l' + y) - \left(x + \frac{l'}{2}\right) = \frac{y - x}{2}.$$

The backward velocity of the gun is $u = \dfrac{dx}{dt}$.

„ forward „ „ shot is $v = \dfrac{dy}{dt}$.

The forward velocity of the mid point of the charge is

$$\frac{d\,\frac{1}{2}(y - x)}{dt} = \frac{u - v}{2} \quad \ldots\ldots\ldots \quad (1).$$

By actual experiment on the laws of Motion.

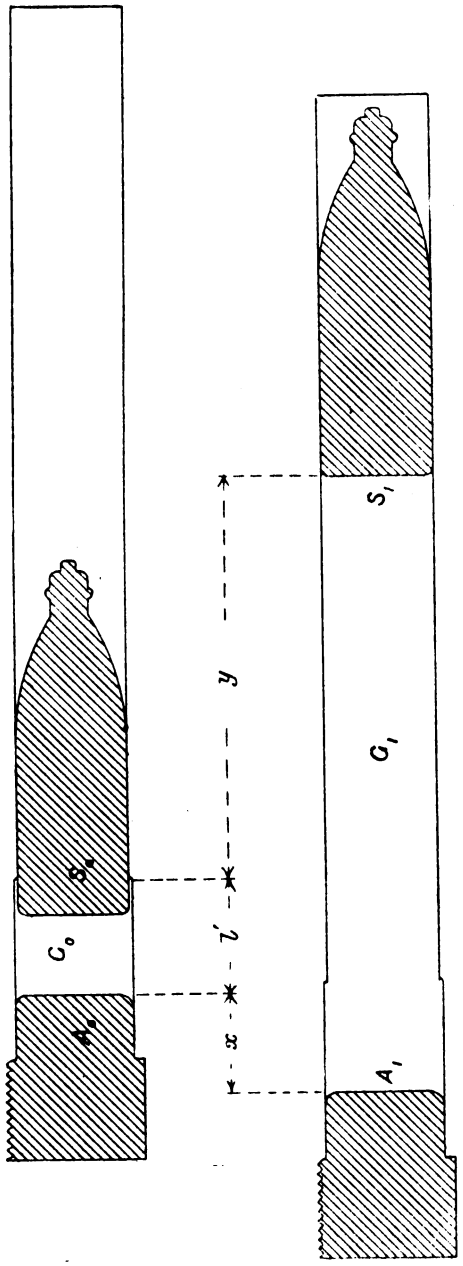

Fig 1.

F lbs. (or tons) acting on W lbs. (or tons) gives a velocity of

$$\frac{F}{W} g \text{ f/s in 1 second,}$$

$$2\frac{F}{W} g \text{ f/s in 2 seconds,}$$

Digitized by Google

$$3\frac{F}{W}g \text{ f/s in 3 seconds,}$$

$$t\frac{F}{W}g \text{ f/s in } t \quad \text{,,}$$

so that the velocity v f/s acquired in t seconds is

$$v = t\frac{F}{W}g = \frac{F}{W}gt,$$

or

$$W\frac{v}{g} = Ft.$$

This gives us the momentum equation, or the momentum generated by a force F lbs. (or tons) acting on W lbs. (or tons) for t seconds.

This equation is at once got from the second law of motion $\frac{F}{W} = \frac{f}{g}$, where f is the acceleration and $f = \frac{v}{t}$, so that we have again $W\frac{v}{g} = Ft$.

Since the acceleration is uniform, therefore the average velocity $\frac{s}{t} = \frac{0+v}{2} = \frac{v}{2}$, where s feet is the distance passed over by W, whilst the force F acts for t seconds.

Hence we have

$$W\frac{v}{g} = Ft \quad \text{and} \quad \frac{s}{t} = \frac{v}{2},$$

so that

$$W\frac{v^2}{2g} = Fs.$$

This is the energy equation, and states that the work done is $W\frac{v^2}{2g}$, being equal to the distance through which W lbs. (or tons) is moved by a force F lbs. (or tons).

Let the

Backward thrust of gas on base of bore be X lb.,
Forward ,, ,, ,, shot be Y lb.
The resultant thrust forward on the gas is X − Y lb.

Then w, W, P lbs. denoting the weights of shot, gun and charge,

$$Xt = W.\frac{u}{g},$$

$$Yt = w\frac{v}{g},$$

$$(X - Y)t = P\frac{\frac{1}{2}(v-u)}{g} \text{ from (1),}$$

so that

$$W\frac{u}{g} - w\frac{v}{g} = P\frac{\frac{1}{2}(v-u)}{g},$$

or

$$(W + \tfrac{1}{2}P)u = (w + \tfrac{1}{2}P)v \quad \ldots\ldots\ldots \quad (2),$$

anywhere along the bore.

Digitized by Google

Also

$$(W + \tfrac{1}{2}P)x = (w + \tfrac{1}{2}P)y \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

$$x = \frac{w + \frac{1}{2}P}{W + w + P}(x + y) \quad . \quad . \quad . \quad . \quad . \quad . \quad (4),$$

$$y = \frac{w + \frac{1}{2}P}{W + w + P}(x + y) \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

At the muzzle $x + y = l$, the length of the rifled part of the bore, so that

$$t = \frac{l}{\frac{1}{2}(V + U)} = \frac{W + \frac{1}{2}P}{W + w + P} \cdot \frac{l}{\frac{1}{2}V} \quad . \quad . \quad . \quad . \quad (6),$$

where V is the muzzle velocity of shot, and U the velocity of recoil when the shot has reached muzzle, so that t is practically $\frac{l}{\frac{1}{2}V}$.

Again

$$Xx = W\frac{v^2}{2g} \text{ ft.-lb.},$$

$$Yy = w\frac{v^2}{2g} \text{ ft.-lb.},$$

anywhere up the bore, so that at the muzzle

$$X\frac{w + \frac{1}{2}P}{W + w + P}l = W\frac{U^2}{2g},$$

$$Y\frac{W + \frac{1}{2}P}{W + w + P}l = w\frac{V^2}{2g},$$

or

$$X = \frac{W + w + P}{w + \frac{1}{2}P}W \cdot \frac{U^2}{2gl} \quad . \quad . \quad . \quad . \quad . \quad . \quad (7),$$

$$Y = \frac{W + w + P}{W + \frac{1}{2}P}w \cdot \frac{V^2}{2gl} \quad . \quad . \quad . \quad . \quad . \quad . \quad (8).$$

It is found practically that the gun and carriage have moved only a very short distance when the projectile has just left the muzzle; and that the maximum velocity of recoil is not attained till a short time afterwards.

For after the shot has left the muzzle the powder gases escape with some unknown high velocity and mingle with the surrounding air, imparting to it a considerable momentum.

Meanwhile the pressure on the base of the bore must last for an appreciable time longer, so that the gun receives an additional recoil after the shot has left the muzzle; and this recoil is greater as the weight of the charge and the powder pressure up to the muzzle is greater.

To allow for this in practice, the empirical formula which is now used for calculating the velocity of recoil is—

$$WU = (w + CP)V \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9),$$

where C is a constant determined by experiment.

Digitized by Google

The value of C is usually taken at from 1·5 to 2, according to the nature of the powder.

From formula (7),

$$\frac{\text{The velocity of the shot}}{\text{,, ,, gun}} = \frac{V}{U} = \frac{W}{w + CP} = \frac{W}{w} \text{ approximately;}$$

$$\frac{\text{the momentum of the shot}}{\text{,, ,, gun}} = \frac{wV}{WU} = \frac{wW}{wW + CWP} = 1 \text{ approximately;}$$

$$\frac{\text{the energy of the shot}}{\text{,, ,, gun}} = \frac{wV^2}{WU^2} = \frac{w}{W}\left(\frac{W}{w + CP}\right)^2 = \frac{W}{w} \text{ approximately,}$$

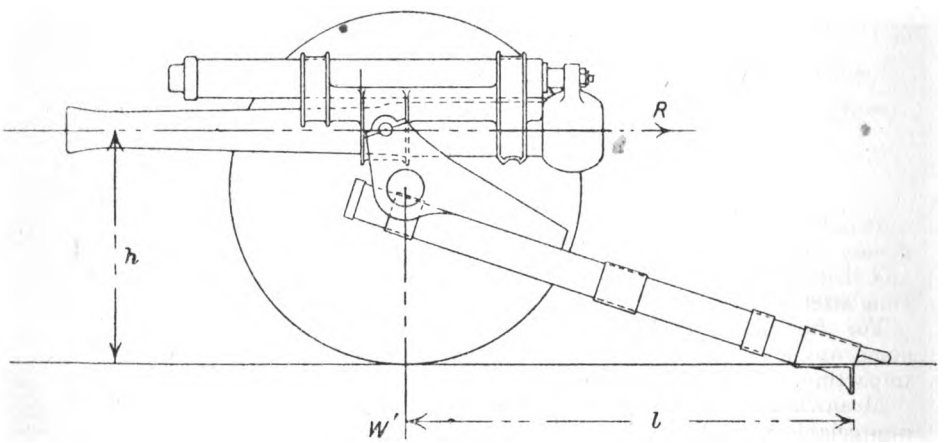
so that the energy of recoil diminishes as the weight of the gun and carriage is increased.

In the modern systems of field artillery the gun has a long recoil in its cradle, and the wheels and trail are required to remain stationary on the ground. The gun is brought up in its recoil on cradle by a hydraulic buffer, and is run out again automatically by the resilience spiral springs.

In this way the carriage does not jump about on the ground, the gun layer can be seated on the carriage under the protection of a shield, and with his sights and elevating gear fixed to the cradle is independent of recoil, and can follow up a target continuously.

During recoil, the gun (fig. 2) exerts a pressure on the carriage which we will call R; suppose the gun to be firing point blank on

Fig. 2.



level ground, and that the height of the axis of the gun is h feet above the ground line, then the lifting moment round the end of the trail is

$$R \times h.$$

Opposing this is $W' \times l$, where W' is the weight on the wheels and l is the distance on ground from the wheels to the point of trail.

To prevent the wheels from jumping, it is necessary that any time

Digitized by Google

during recoil the *lifting* moment shall not exceed the stability moment, so that

$$R \cdot h < W' \cdot l,$$

and, in the limiting case

$$Rh = W'l \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10).$$

To prevent jump of wheels, therefore, we can either—

(*a*) Increase the weight of carriage;
(*b*) Reduce the height of the gun from the ground;
(*c*) Increase the length of the trail, keeping the centre of gravity as far forward as possible;
(*d*) Reduce the reaction R on the carriage;

Method (*d*) is the most suitable one.

The recoiling gun has acquired a certain amount of energy. The duty of the buffer is to absorb this energy with as little shock as possible.

From equation (9)

$$WU = (w + CP)V,$$

from which the velocity of recoil U is obtained.

W = weight of recoiling parts in lbs.
w = ,, shot in lbs.
V = muzzle velocity of shot in f/s.
P = weight of charge in lbs.
C is generally 2.

From the above equation, it is seen that if w, P, and V are fixed, then by increasing W we decrease U; so that the greater the weight of the recoiling parts the less the velocity of recoil; in the 13 and 18-pr. Q F. guns, the buffer cylinder recoils with the gun, and so adds to the weight of the recoiling parts.

The energy of recoil is

$$W \frac{U^2}{2g} = R_1 S;$$

where

R_1 is the average resistance of the buffer in lbs.
S is the length of recoil in feet.

It is seen therefore from this equation that by increasing S, we can decrease R_1. The maximum resistance R does not vary much from R_1.

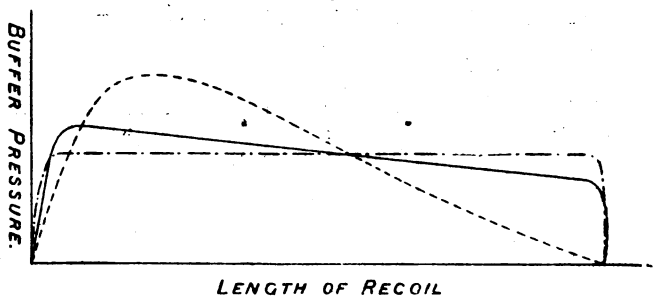
The action of a long recoil gun on firing is as follows:—

The gun recoils through the cradle, drawing with it the buffer cylinder and compressing the springs. The oil passes from front to rear of the piston round it, the clearance afforded by the grooves being such as to offer the required hydraulic resistance. This is so arranged that the pull on the piston rod is never sufficient to cause the carriage to lift about the point of the trail. As the gun recoils, the centre of gravity of the whole gun and carriage becomes displaced to the rear, thereby lessening the actual weight on the wheels and increasing that on the trail; consequently, as W′ decreases (see formula 10), the stability moment decreases. In order to preserve the stability of the carriage, the lifting moment must be decreased, and this can only be done by lessening the resistance of the piston.

Digitized by Google

Looking at the subjoined diagram (fig. 3) the horizontal distance from left to right represents the travel of the gun during recoil, while the vertical heights represent the buffer pressure and therefore the pull of the piston rod. The dotted curve represents roughly the pressure line of a buffer with uniform clearance; the chain dot line

Fig. 3.



that of a buffer with uniform resistance; and the plain line that of the buffer required for a field carriage. The area enclosed by each curve will therefore represent the work done by the buffer. Observe that all three areas are equal since the total of work is the same in each case, only differently distributed. In the above considerations all mention of the spring has been omitted for the sake of simplicity. In reality their pull has to be added to that of the buffer, and it is the combined pull that has to be regulated.

The limiting conditions for the stability of a carriage are given by

$$W'l = Rh \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11),$$

$$WU = (w + 2P)V \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12),$$

$$W\frac{U^2}{2g} = RS \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13),$$

where W' = weight on wheels with gun run up.

These equations are laid down for the gun at 0° elevation, since, if the carriage has sufficient stability at that elevation, it will have greater stability at all positive elevations.

For a long recoil fixed carriage, Mr. A. G. Hadcock, late R.A., gives the following solution to the question:—

Is the stability of the carriage affected by the position of the recoil cylinder?

The force of recoil of the gun, &c., is

$$R = W\frac{U}{gt} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14),$$

and the pull on the buffer

$$= W\frac{U^2}{2gs} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (15).$$

We may assume that, as U varies from a maximum U to zero at the end of recoil of S feet, the mean recoil velocity is $\frac{U}{2}$.

$$\therefore \frac{U}{2}t = S \quad \text{or} \quad \frac{U^2}{2S} = \frac{U}{t} \quad . \quad . \quad . \quad . \quad . \quad . \quad (16).$$

Digitized by Google

The pull on the buffer therefore equals R.

In fig. 4 the buffer cylinder is above the gun, and in fig. 5 it is below the gun.

In both cases, take moments about A, we have the pull of the buffer about AC, and a couple of moment R, BC and W′ varies as the gun recoils.

Fig. 4.

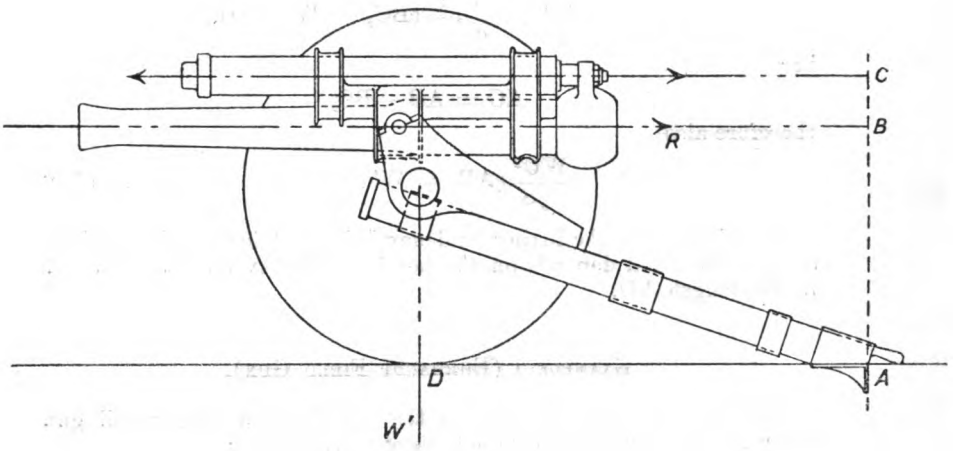


Fig. 5

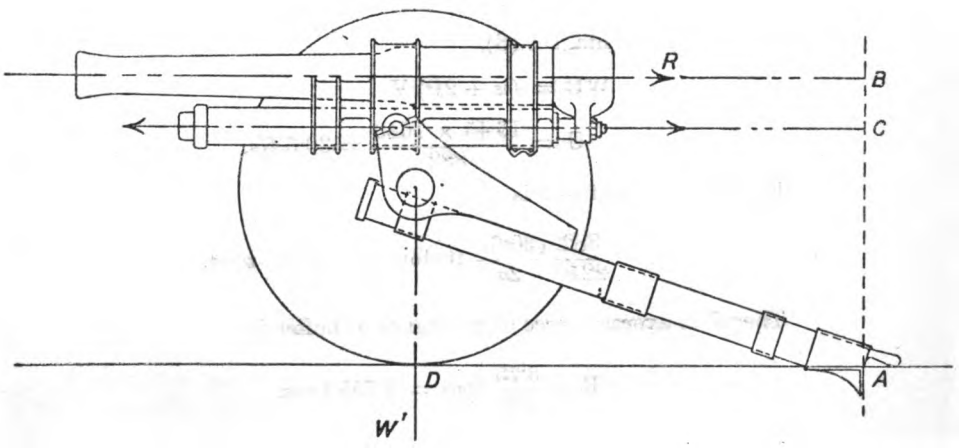


From fig. 4 and equations (14), (15),

$$\frac{WU^2}{2gS}(AC) - \frac{W}{g} \cdot \frac{U}{t}(BC) = W' \cdot (AD),$$

Digitized by Google

therefore from (16)

$$\frac{WU^2}{2gS}(AB + BC) - \frac{W}{2g}.\frac{U^2}{S}(BC) = W'.AD.$$

$$\therefore \frac{WU^2}{2gS}(AB) = W'.(AD) \quad . \quad . \quad . \quad . \quad (17);$$

from fig. 5 we have

$$\frac{WU^2}{2gS}(AC) + \frac{W}{g}.\frac{U}{t}(BC) = W'(AD),$$

here

$$AC = AB - BC,$$

therefore also

$$\frac{WU^2}{2gS}(AB) = W'(AD) \quad . \quad . \quad . \quad . \quad . \quad . \quad (18).$$

This shows that the lifting tendency is independent of the position of the buffer and depends on the height of the axis of the gun and on the length AD.

EXAMPLE 1 (EHRHARDT FIELD GUN).

Find the minimum weight on the wheels of a long recoil gun carriage, which will keep the wheels steady, given

Weight of shot; $w = 14{\cdot}25$ lbs.; $h = 3{\cdot}28$ feet.
Weight of charge; $P = 1{\cdot}1$ lbs.; $l = 8{\cdot}2$ feet.
Weight of recoiling parts; $W = 882$ lbs.
Muzzle velocity; $V = 1640$ f/s.
Length of recoil 3·28 feet.

Equating momenta, see (8),

$$WU = (w + 2P)V$$

$$U = \frac{16{\cdot}45 \times 1640}{882} = 30{\cdot}6 \text{ f/s.}$$

Kinetic energy of gun is

$$\frac{882}{2240}\frac{(30{\cdot}6)^2}{2g} \text{ ft.-tons} = 5{\cdot}75 \text{ ft.-tons.}$$

Therefore average force of resistance of buffer is

$$R = \frac{5{\cdot}75}{3{\cdot}28} \text{ tons} = 1{\cdot}755 \text{ tons.}$$

The minimum weight, W', on the wheels to keep them from lifting is got from

$$W' \times 8{\cdot}2 = 1{\cdot}755 \times 3{\cdot}28$$

$$W' = \frac{5{\cdot}75}{8{\cdot}2} = 0{\cdot}7 \text{ ton} = 14 \text{ cwt.} = 1568 \text{ lbs.}$$

Digitized by Google

EXAMPLE 2.

For the 18-pr. Q.F.

W′, weight on wheels (gun in forward position) = 23 cwt. = 2576 lbs.
weight on trail = 120 lbs.
W, { weight of gun = 9 cwt.
{ weight of buffer cylinder = 40 lbs. $\therefore$ W = 1048 lbs.
h, height of axis of horizontal gun from ground = 36·86 inches.
l, distance along ground from wheel to point of trail = 9·15 inches.
w, weight of shot = 18·5 lbs.
P, weight of charge = $1\frac{7}{16}$ lbs.
V, the muzzle velocity = 1658 f/s.

The maximum recoil possible is S = 49 inches.

Find the minimum length of recoil allowable to keep the wheels steady.

In this example the weight of the springs in cylinder is left altogether out of account, also W′ is taken as 2576 throughout recoil.

We have to find S, the length of recoil.

$$WU = (w + 2P)\,V,$$

$$\therefore U = \frac{18{\cdot}5 + 2{\cdot}9}{1048}\,1658,$$

$$= 33{\cdot}86 \text{ f/s.}$$

Energy to be absorbed is

$$W\,\frac{U^2}{2g} = R \times S,$$

also

$$W' \times l = R \times h, \quad \text{or} \quad R = \frac{W' l}{h}.$$

From these two equations, by eliminating R,

$$W\,\frac{U^2}{2g} = \frac{W' \times l}{h} \times S.$$

$$\therefore S = \frac{W}{W'} \cdot \frac{U^2}{2g} \cdot \frac{h}{l}$$

$$= \frac{1048 \times (33{\cdot}86)^2 \times 36{\cdot}86}{64 \times 2576 \times 91{\cdot}5} \text{ ft.}$$

$$= 2{\cdot}936 \text{ ft.}$$

$$= 35{\cdot}23 \text{ inches.}$$

Hence, since 49 inches of recoil is allowed, there is a margin on the side of stability of the carriage.

EXAMPLE 3.

In Example 2, the data are the same, except that the gun is in the most unfavourable position for stability; this is when it has recoiled its full length. In this case the weight on the wheels is 1972 lbs.; so that W′ = 1972.

Digitized by Google

Find the necessary recoil of the gun for stability.
As in Example 2,

$$U = 33{\cdot}86 \text{ f/s},$$

also

$$S = \frac{W}{W'} \cdot \frac{U^2}{2g} \cdot \frac{h}{l}$$
$$= \frac{1048 \times (33{\cdot}86)^2 \times 36{\cdot}86}{64 \times 1972 \times 91{\cdot}5} \text{ ft.}$$
$$= 3{\cdot}83 \text{ ft.}$$
$$= 45{\cdot}96 \text{ inches.}$$

It is seen from Examples 2 and 3 that 49 inches of recoil is ample for stability, even when the weight on the wheels is least.

If the springs are taken into account, the length of recoil calculated as necessary for stability will not be found to vary much.

EXAMPLE 4.

Taking the weight of the inner spring as 71 lbs. and the weight of the outer spring as 91 lbs.

Then if each spring is compressed to one-half its original length, and U f/s be the velocity of recoil, the velocity of recoil of the springs will be $\frac{3}{4}U$, $\frac{1}{4}U$ respectively (see figs. 7, 8).

Taking these into account, the momentum equation becomes

$$(1048 + \tfrac{3}{4}.71 + \tfrac{1}{4}.91)\, U = (w + 2P)\, V.$$

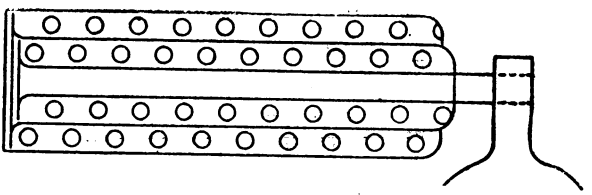
The energy equation is

$$1043 \frac{U^2}{2g} + \frac{71\,(\frac{3}{4}U)^2}{2g} + 91 \frac{(\frac{1}{4}U)^2}{2g} = RS.$$

Find the value of S, the least recoil necessary for stability.

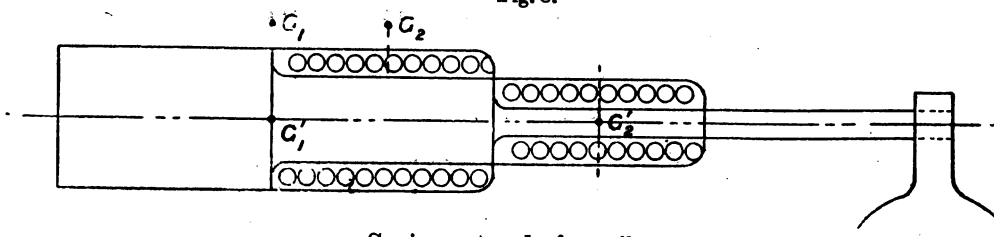
Answer 32·784 inches.

Fig. 7.



Springs before firing.

Fig. 8.



Springs at end of recoil.

CHAPTER V.
PRINCIPLES OF GUN CONSTRUCTION.

SECTION I.—STRESSES IN THE MATERIAL OF A GUN.

A GUN is essentially a thick tube, which is reinforced at any part according to the internal pressure to be expected there.

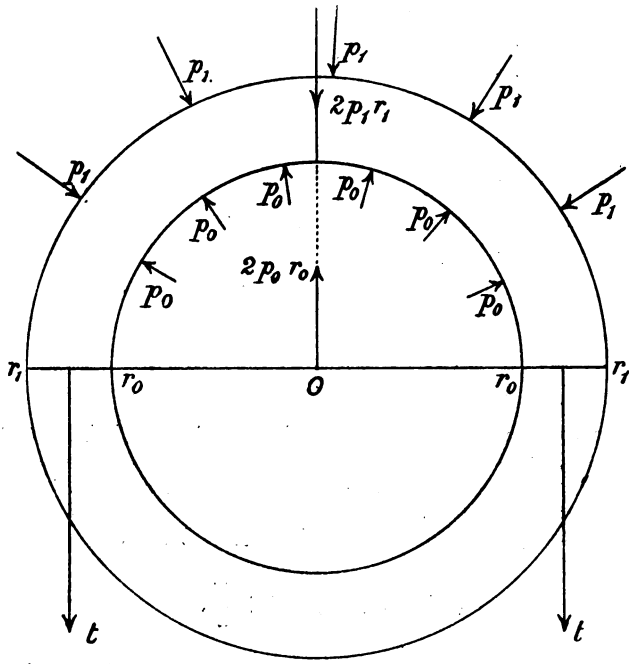
After the determination of the maximum pressure to be expected in the chamber of a gun and at various distances up the bore, the gunmaker is required to proportion the thickness of the metal of the gun so as to withstand the pressure with safety.

The theoretical problem is then the determination of the state of stress set up in the metal of a thick cylindrical tube, due to arbitrary internal and external pressure; and to determine this the tube is supposed cut in half by a diametral plane $r_1r_0Or_0r_1$, and the equilibrium of either half is considered.

The inch and ton are the units employed in practice, or else the centimetre and kilogramme in metric units.

Suppose then that the internal and external radii of the tube are r_0 and r_1 inches (cm.), and that the tube is subject to steadily applied internal and external pressures of p_0 and p_1 tons/in.^{2} [kg./cm.^{2} or atmospheres], see fig. 1.

Fig. 1.



Considering an inch length of the tube, the hydrostatic thrust of the interior pressure p_0 over the interior semicircular surface is the same as the thrust across the diametral plane r_0Or_0, and is therefore $2r_0p_0$ tons; so also the thrust of the pressure p_1 over the exterior semicircle is $2r_1p_1$ tons, in the opposite direction.

Digitized by Google

And if X denote the pull in tons across each section of the tube, then the forces acting on the upper semicircle are $2p_0r_0$ in one direction and $2r_1p_1$, 2X in the opposite direction; these are in equilibrium.

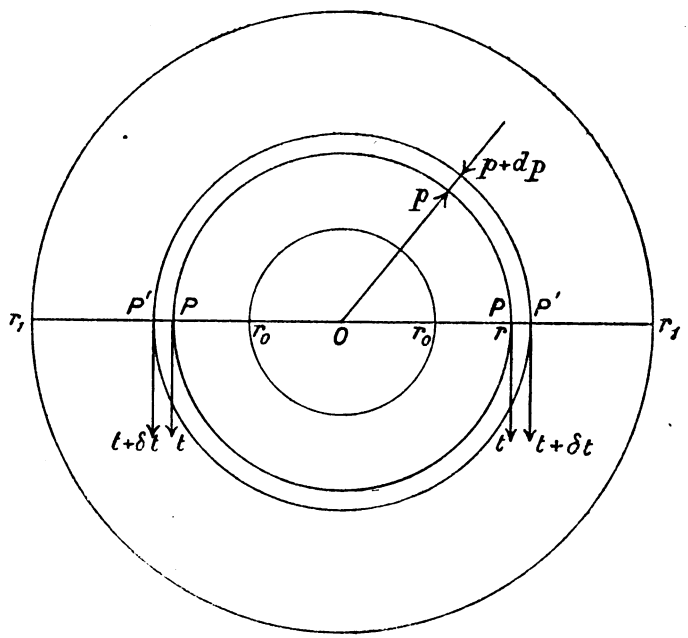
$$\therefore 2X = 2p_0r_0 - 2p_1r_1,$$

or

$$X = p_0r_0 - p_1r_1.$$

Next to find the equations which connect the internal and external thrusts at any point in the tube with the pull or tension of the metal at the same place.

Fig. 2.



Take the very thin cylinder bounded by PP and P'P', let OP = r, OP' = $r + \delta r$, so that δr is v small. Let the internal pressure be p and the external $p + \delta p$, so also let the tension at P be t tons/in.^{2}, and at P', $(t + \delta t)$ tons/in.^{2}

Then PP' = δr, and the mean tension across PP' is

$$\tfrac{1}{2}(t + t + dt) = t + \frac{\delta t}{2},$$

and this acts on an area of δr square inches; hence the total pull is twice

$$\left(t + \frac{\delta t}{2}\right)\delta r, \text{ i.e., } = 2\left(t + \frac{\delta t}{2}\right)\delta r.$$

Digitized by Google

Considering the equilibrium of the thin cylinder PP′ we have therefore

$$2pr = 2(p + \delta p)(r + \delta r) + 2\left(t + \frac{\delta t}{2}\right)\delta r$$

i.e.,

$$(p + t)\,\delta r + r\delta p = 0,$$

or

$$P + t = -r\frac{\delta p}{\delta r} \quad \ldots\ldots \quad (1).$$

In Part II. it is also shown that

$$t - p = \text{const.} = 2b, \text{ say} \quad \ldots\ldots \quad (II).$$

From Equations I and II, by very elementary calculus,

$$p = \frac{a}{r^2} - b \quad \ldots\ldots\ldots \quad (III),$$

$$t = \frac{a}{r^2} + b \quad \ldots\ldots\ldots \quad (IV),$$

where a and b are constants.

These two equations are fundamental to the whole subject; they give us the equations for the Barlow curves, and by means of III and IV we can find the pressures and tensions at any point in the tube of a gun as soon as the a, b are known.

In Part II a geometrical method of drawing these Barlow curves is shown.

EXAMPLE TO FIND a, b.

If the internal pressure p_0 of a tube be known and also the external pressure p_1, a and b are at once found.

The value p_0 holds good where $r = r_0$ in (III).

$$\therefore\ p_0 = \frac{a}{r_0^2} - b. \quad \text{So also } p_1 = \frac{a}{r_1^2} - b = 0 \text{ say,}$$

then

$$a\left(\frac{1}{r_0^2} - \frac{1}{r_1^2}\right) = p_0, \quad \text{since} \quad b = \frac{a}{r_1^2}$$

$$\left.\begin{aligned} \therefore\ a &= \frac{r_1^2 r_0^2}{r_1^2 - r_0^2}\,p_0 \\ b &= \frac{r_0^2}{r_1^2 - r_0^2}\,p_0 \end{aligned}\right\}$$

whence also

$$p = \frac{a}{r^2} - b,$$

or

$$p = p_0\frac{r_0^2}{r_1^2 - r_0^2}\left(\frac{r_1^2}{r^2} - 1\right) = p_0\frac{r_0^2}{r^2}\cdot\frac{r_1^2 - r^2}{r_1^2 - r_0^2} \quad \ldots \quad (V),$$

so

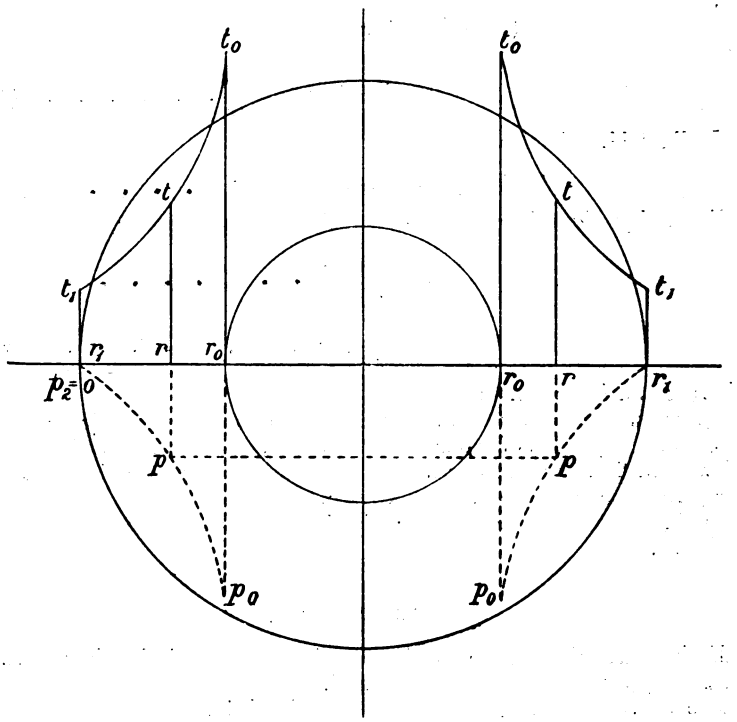
$$t = p_0\frac{r_0^2}{r_1^2 - r_0^2}\left(\frac{r_1^2}{r^2} + 1\right) = p_0\frac{r_0^2}{r^2}\cdot\frac{r_1^2 + r^2}{r_1^2 - r_0^2} \quad \ldots \quad (VI),$$

and this gives the pressure and tension at any point of a tube when p_0 is known and $p_1 = 0$.

Digitized by Google

The curves of pressure p and the tension t of a tube or cylinder are shown on fig. 3.

Fig. 3.



The curve of tension is got from $t = \frac{a}{r^2} + b$ and the ordinates t are drawn above and perpendicular to the diameter $r_1 r_0 O r_0 r_1$ (see fig. 3).

The curve of pressure is got from $p = \frac{a}{r^2} - b$ and the ordinates p are drawn below the diameter.

And the two curves are seen to be one a reflex of the other.

Also it is seen from the equations that a and b, being both positive, both t and p are greatest when r is least, *i.e.*, when $r = r_0$, and that they decrease as r increases and are least when r is greatest, *i.e.*, when $r = r_1$.

From p. 152, then, considering the equilibrium of the whole tube,

$$\text{area } t_0 r_0 r_1 t_1 \left[\text{or } \int_{r_0}^{r_1} t\, dr \right] = p_0 r_0 - p_1 r_1$$

$$= \text{area } r_0 p_0 p_0 r_0, \text{ since } p_1 = 0.$$

And for the equilibrium of any part, say that between r_0 and r, we have similarly

$$\text{area } t_0 r_0 r t \left[\text{or } \int_{r_0}^{r} t\, dr \right] = \text{rectangle } r_0 p_0 - \text{rectangle } r p.$$

Digitized by Google

When the thickness of the tube is small compared with the diameter, the maximum and minimum hoop tension differ only slightly from the average; so that this average need only be considered, as in the case of the cylindrical shell of a steam boiler.

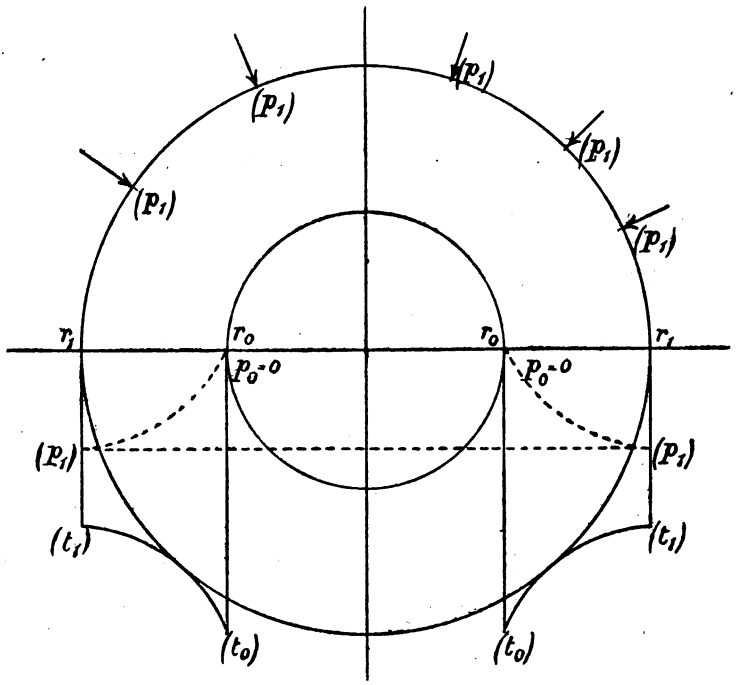
In gun construction, however, the maximum hoop tension must be carefully considered, so as to keep it well below the elastic limit (p. 7); the shape of the curve of hoop tension $t_0 t t_1$ must therefore be determined, and at the same time the curve of radial pressure $p_0 p p_1$.

According to the rules laid down by the Ordnance Committee, the maximum allowable hoop tension is 18 tons/in.^{2} in a hoop or jacket, reduced to 15 tons/in.^{2} for an internal A tube, to allow for the diminution in strength due to rifling and erosion.

From fig. 3 we see that if the tube be unsupported by outside hoops, the tension t_0 at r_0 limits the pressure p_0 that the tube can stand on firing; suppose t_0 to be the working tenacity of the metal, then the fibre at r_0 is bearing the full strain, but the rest of the tube is bearing a strain which is smaller, and smaller than what it is capable of supporting; in other words, the metal of the tube could stand a good deal more strain if this were more evenly distributed.

The method adopted to secure this more even distribution of strain or hoop tensions is that of shrinking on outer tubes, so that each outer tube grips the inner one with a certain radial pressure.

Fig. 4.



Due to the radial pressure p_1, the tensions between r_0 and r_1 are negative, that is, are compressions, and these are shown on the under side of $r_1 r_0 r_0 r_1$ to express diagrammatically the negative value.

Digitized by Google

Suppose now our tube were supported by such an outer tube, and that the radial pressure between the surfaces is (p_1) tons/in.^{2}. The effect of this on our tube will now be considered.

The pressures (p_1) act as shown at the circumference r_1r_1; to find the pressure and tension at any point r in the tube, see fig. 6.

From the fundamental equations (III), (IV),

$$(p_1) = \frac{a}{r_1^2} - b,$$

$$0 = (p_0) = \frac{a}{r_0^2} - b,$$

whence

$$\left.\begin{aligned} a &= -\frac{r_0^2 r_1^2}{r_1^2 - r_0^2}(p_1) \\ b &= -\frac{r_1^2}{r_1^2 - r_0^2}(p_1) \end{aligned}\right\} a, b \text{ are therefore both negative.}$$

At any point r

$$(t) = \frac{a}{r^2} + b$$

or

$$(t) = -\frac{r_1^2}{r^2}\cdot\frac{r^2 + r_0^2}{r_1^2 - r_0^2}(p_1) \quad . \quad \text{(VII)},$$

so

$$(p) = \frac{a}{r^2} - b \quad \text{or} \quad (p) = \frac{r_1^2}{r^2}\cdot\frac{r^2 - r_0^2}{r_1^2 - r_0^2}(p_1) \quad . \quad \text{(VIII)}.$$

It is seen that (t) must always be negative; this means that the effect of (p_1) is to create hoop compressions inside the tube, instead of tensions. (t), being negative, is drawn below $r_1 0 r_1$ in the direction opposite to the positive direction; it is also seen that (t) increases as r decreases, and that therefore the compression is greatest at r_0 and least at r_1 (see fig. 6).

Combining diagrams 5 and 6, we see that when a hoop is shrunk on the tube the original tensions t are greatly decreased, especially t_0; and that therefore a much greater powder pressure p_0 can be safely used.

An example showing this is now worked out.

Take the cross-section of the A tube of an early 4·7-inch gun at the cartridge chamber, where the bore is 5 inches in diameter and the thickness of metal 1·6 inches, so that $r_0 = 2{\cdot}5$; $r_1 = 4{\cdot}1$ inches.

We are limited by $t_0 = 15$ tons/in.^{2}

1st. Suppose the tube has an outer tube over it put on without shrinkage, merely a close mechanical fit, then $(p_1) = 0$, and (see fig. 6) from (VII) and (VIII)

$$(t) = 0, \quad (p) = 0.$$

2nd. Suppose the outer tube is shrunk on the inner one, so that it

Digitized by Google

grips it all round with a radial pressure (p_1) = 3 tons/in.^{2}, then the effect of this p_1 at r_0 and at r_1 is as follows:—

From (VII)

$$(t_0) = -\frac{r_1^2}{r_0^2}\cdot\frac{r_0^2+r_0^2}{r_1^2-r_0^2}3 = -9{\cdot}545,$$

$$(t_1) = -\frac{r_1^2}{r_1^2}\cdot\frac{r_1^2+r_0^2}{r_1^2-r_0^2}3 = -6{\cdot}55,$$

so that the original tensions at r_0 and r_1 on firing the gun get reduced by

$$9{\cdot}545 \text{ and } 6{\cdot}55 \text{ tons/in.}^2,$$

and therefore a greater powder pressure can now be used.

In a gun consisting of a tube and a hoop which has been shrunk on it, let the firing pressure p_0 be such that the limits $t_0 = 15$, $t_1 = 18$ tons/in.^{2} are reached, then, considering the outer tube or hoop,

$$p_2 = 0 = \frac{a}{r_2^2} - b,$$

$$t_1 = 18 = \frac{a}{r_1^2} + b,$$

and

$$p_1 = \frac{a}{r_1^2} - b,$$

so that

$$p_1 - p_2 = a\left(\frac{1}{r_1^2} - \frac{1}{r_2^2}\right) = a\frac{r_2^2 - r_1^2}{r_1^2 r_2^2},$$

$$t_1 + p_2 = a\left(\frac{1}{r_1^2} + \frac{1}{r_2^2}\right) = a\frac{r_2^2 + r_1^2}{r_1^2 r_2^2},$$

$$\therefore\ p_1 - p_2 = \frac{r_2^2 - r_1^2}{r_2^2 + r_1^2}(t_1 + p_2),$$

or

$$p_1 = \frac{r_2^2 - r_1^2}{r_2^2 + r_1^2}(t_1 + p_2) + p_2 \quad . \ . \ . \ . \quad \text{(IX)}.$$

In this case, since $p_2 = 0$, $t_1 = 18$,

$$p_1 = \frac{r_2^2 - r_1^2}{r_2^2 + r_1^2}18,$$

which gives the value of p_1, the radial pressure between the tube and the hoop.

Referring to IX, this is the gunmaker's formula. In its most general form this is

$$p_n = \frac{r^2_{n+1} - r_n^2}{r^2_{n+1} + r_n^2}(t_n + p_{n+1}) + p_{n+1} \text{ for the } (n+1)^{\text{th}} \text{ hoop (the outer hoop)},$$

this is derived from knowing t_n, p_{n+1};

Digitized by Google

$$t_n = \frac{a}{r_n^2} + b,$$

$$p_{n+1} = \frac{a}{r^2_{n+1}} - b,$$

$$p_n = \frac{a}{r_n^2} - b,$$

whence

$$p_n - p_{n+1} = \frac{a}{r_n^2 r^2_{n+1}}(r^2_{n+1} - r_n^2),$$

$$t_n + p_{n+1} = \frac{a}{r_n^2 r^2_{n+1}}(r^2_{n+1} + r_n^2),$$

$$\therefore \frac{p_n - p_{n+1}}{t_n + p_{n+1}} = \frac{r^2_{n+1} - r_n^2}{r^2_{n+1} + r_n^2},$$

$$p_n = \frac{r^2_{n+1} - r_n^2}{r^2_{n+1} + r_n^2}(t_n + p_{n+1}) + p_{n+1} \quad . \quad . \quad . \quad (X).$$

This formula is of great importance.

It is necessary to have distinguishing symbols for different stresses set up in a gun.

Powder stresses are those set up by the radial pressures of the powder gas throughout the mass of the gun, the symbols for these will be P, T.

The initial stresses are those set up by the shrinking on of one tube or hoop over another, the symbols for these are (p), (t).

The firing stresses are those which are created in the made up gun when the powder charge is fired, it is therefore made up of both the powder and the initial stresses ; the symbols for these are p, t.

So that

Firing stress = Powder stress + Initial stress.

Summing up, the symbols are

Powder stresses P, T.
Firing stresses p, t.
Initial stresses (p), (t).

Powder Stress.

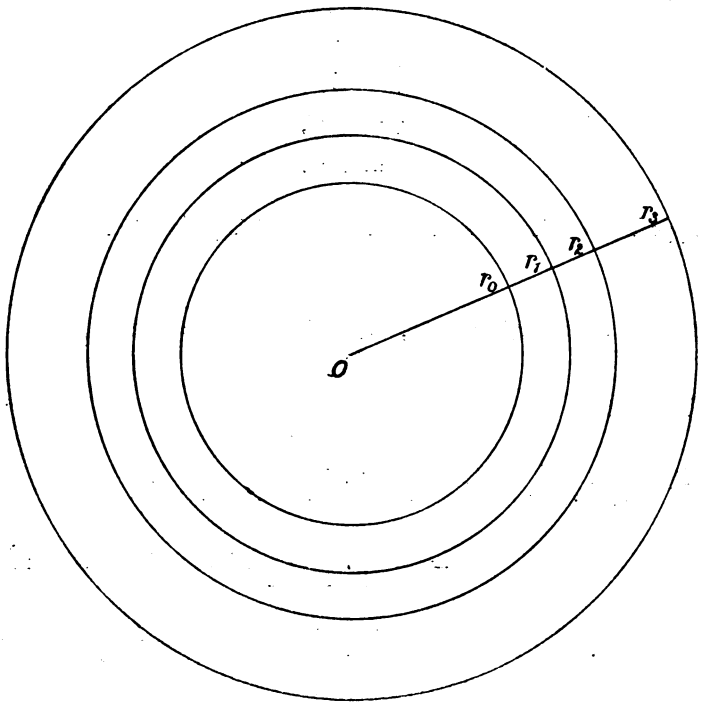
In dealing with these, all consideration of the initial stresses in the completed gun is left alone, the problem then amounts to this :—

A pressure P_0 is applied at the interior of the tube. Let the gun consist of a tube and 3 hoops : what will be the radial pressure and circumferential tension produced at any part of the gun, due to the powder pressure P_0 ?

In dealing with this, the whole gun is considered as one homogeneous cylinder of internal radius r_0 and external radius r_3, as though the surfaces of separation between any two hoops did not exist. This holds good no matter how many hoops the gun may have.

Digitized by Google

Fig. 5.



The data to start with are: P_0 is known, P_3 is zero, r_0, r_1, r_2, r_3 are known.

$$P_0 = \frac{a}{r_0^2} - b, \quad \text{whence} \quad a = \frac{r_3^2 r_0^2}{r_3^2 - r_0^2} P_0,$$

$$0 = P_3 = \frac{a}{r_3^2} - b, \qquad b = \frac{r_0^2}{r_3^2 - r_0^2} P_0.$$

Substituting these values of a and b in

$$P_r = \frac{a}{r^2} - b,$$

$$T_r = \frac{a}{r^2} + b,$$

we have

$$(P_r, \text{ or}) \; P = \frac{r_0^2}{r^2} \cdot \frac{r_3^2 - r^2}{r_3^2 - r_0^2} P_0 \quad . \quad . \quad . \quad . \quad \text{(XI)},$$

$$(T_r, \text{ or}) \; T = \frac{r_0^2}{r^2} \cdot \frac{r_3^2 + r^2}{r_3^2 - r_0^2} P_0 \quad . \quad . \quad . \quad . \quad \text{(XII)},$$

and from this we have at once the radial pressure and the circumferential tension at any distance.

Digitized by Google

As an example, take a 6-inch gun composed of an A tube, breech piece B and jacket C, where

$$r_0 = 4,$$
$$r_1 = 5{\cdot}6,$$
$$r_2 = 8{\cdot}7,$$
$$r_3 = 11{\cdot}8.$$

Suppose a powder pressure of 16 tons/in.^{2} is given, *i.e.*,

$$P_0 = 16.$$

Then, $r_0^2 = 16$, $r_1^2 = 31{\cdot}36$, $r_2^2 = 75{\cdot}69$, $r_3^2 = 139{\cdot}24$, and

$$P_0 = 16,$$

$$P_1 = \frac{r_0^2}{r_1^2} \cdot \frac{r_3^2 - r_1^2}{r_3^2 - r_0^2} 16 = \frac{16}{31{\cdot}36} \cdot \frac{139{\cdot}24 - 31{\cdot}36}{139{\cdot}24 - 16} 16$$

$$= \frac{16}{31{\cdot}36} \cdot \frac{107{\cdot}88}{123{\cdot}24} 16 = 7{\cdot}13 \text{ (by slide rule)},$$

$$= \frac{r_0^2}{r_2^2} \cdot \frac{r_3^2 - r_2^2}{r_3^2 - r_0^2} 16 = \frac{16}{75{\cdot}69} \cdot \frac{63{\cdot}55}{123{\cdot}24} 16 = 1{\cdot}745 \text{ (by slide rule)},$$

$$P_3 = \frac{r_0^2}{r_3^2} \cdot \frac{r_3^2 - r_3^2}{r_3^2 - r_0^2} 16 = 0.$$

$$T_0 = \frac{r_0^2}{r_0^2} \cdot \frac{r_3^2 + r_0^2}{r_3^2 - r_0^2} 16 = \frac{155{\cdot}24}{123{\cdot}24} 16 = 20{\cdot}14 \text{ (by slide rule)},$$

$$T_1 = \frac{16}{31{\cdot}36} \cdot \frac{170{\cdot}6}{123{\cdot}24} 16 = 11{\cdot}28 \quad ,,$$

$$T_2 = \frac{16}{75{\cdot}69} \cdot \frac{214{\cdot}93}{123{\cdot}24} 16 = 5{\cdot}9 \quad ,,$$

$$T_3 = \frac{16}{139{\cdot}24} \cdot \frac{2 \times 139{\cdot}24}{123{\cdot}24} 16 = \frac{16 \times 2 \times 16}{123{\cdot}24} = 4{\cdot}15 \quad ,,$$

In actually working these results, a good deal of labour can be saved by observing that

$$T - P = \left(\frac{a}{r^2} + b\right) - \left(\frac{a}{r^2} - b\right) = 2b,$$

so that the difference between the T and P at any point is constant and equal to $2b$.

$$\therefore T_0 - P_0 = T_1 - P_1 = T_2 - P_2 = T_3 - P_3 = 2b \quad . \text{ (XIII)}.$$

Digitized by Google

As soon as T_0 is found we get at once

$$T_0 - P_0 = 20{\cdot}14 - 16 = 4{\cdot}14 = 2b,$$

so that from (XIII)

$$T_1 = P_1 + 4{\cdot}14 = 7{\cdot}13 + 4{\cdot}14 = 11{\cdot}27,$$
$$T_2 = P_2 + 4{\cdot}14 = 1{\cdot}745 + 4{\cdot}14 = 5{\cdot}885,$$
$$T_3 = P_3 + 4{\cdot}14 = 4{\cdot}14.$$

The very slight differences in the two sets of values for T_1, T_2, T_3 are immaterial; going to one place of decimals, the results are

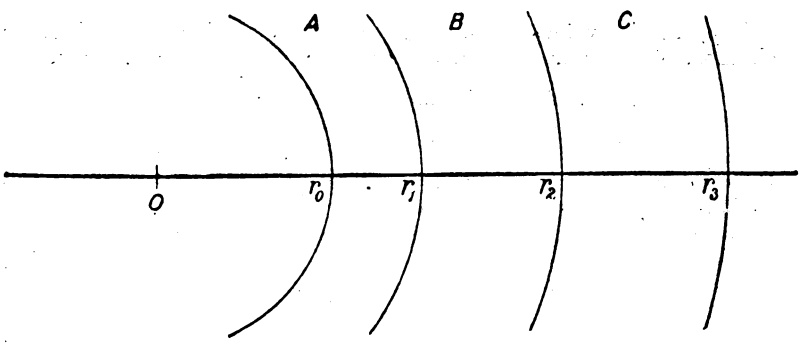
$P_0 = 16$	tons/in.^{2}	$T_0 = 20{\cdot}1$	tons/in.^{2}
$P_1 = 7{\cdot}1$	,,	$T_1 = 11{\cdot}3$	,,
$P_2 = 1.7$	,,	$T_2 = 5{\cdot}9$	,,
$P_3 = 0$	,,	$T_3 = 4{\cdot}1$	,,

Initial Stress (p), (t).

In these, and therefore also in the firing stresses (since they include the initial stresses), there is not a continuity of circumferential stress at the surfaces of separation between any two hoops, and the hoop tension can change suddenly.

Thus, suppose a gun made up of a tube and two hoops of radii $r_0 r_1 r_2 r_3$; call these three tubes A, B, and C.

Fig. 6.



B and C are shrunk on and therefore in a state of repose of the gun,

At the surface of separation between B and C,

C is in tension circumferentially at r_2,

B is in compression circumferentially at r_2.

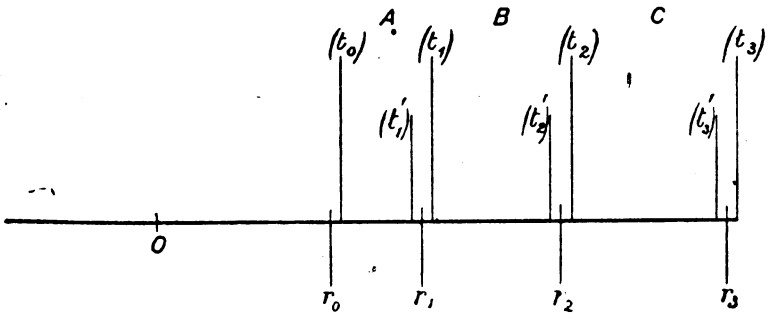
So that sudden changes of circumferential stress do occur at the surfaces of separation.

Digitized by Google

It is necessary to use different symbols for each surface between two hoops, as follows:—

(t_0), (t_1), (t_2), (t_3), (t_4), &c., for the inner surface of each hoop.
(t'_1), (t'_2), (t'_3), &c. „ outer „ „ „

Fig. 7.



So that (t_0) and (t'_1) apply to tube A,
(t_1) „ (t'_2) „ „ B,
(t_2) „ (t'_3) „ „ C.

(t_3) is outside C and therefore does not enter with a gun of 3 tubes only.

Radially the pressure is the same at the surface of separation, so that there is no need of suffixed symbols for the radial stress.

Firing Stresses p, t.

Suppose the values r_0, r_1, r_2, r_3, &c. at any section of the bore or chamber of a gun are known, we have two limits assigned, viz.:—

Tension of material for inner tube is 15 tons/in.^{2},
„ „ „ outer tubes is 18 tons/in.^{2},

then to find the firing stresses at any part of the section in the various hoops, we start with the outer hoop of the gun, and working inwards are enabled to find the maximum pressure in the bore; this maximum pressure is our maximum powder pressure, and knowing this the various powder stresses are found.

Deducting the powder stresses from the firing stresses gives the initial stresses, and then the amount of shrinkage is calculated which will produce the required initial stresses.

The maximum allowable pressure p_0 inside the gun is theoretical. As a matter of precaution no gun is allowed to be subjected to the full amount calculated, the charges being so arranged that the pressure shall not exceed a normal chamber pressure varying from $\frac{2}{3}$ to $\frac{1}{2}$ of this p_0, so that under ordinary conditions the elastic limit of no part of the material may be reached, or permanent extension take place. Thus if it is found that $p_0 = 20$ tons/in.^{2}, the working pressure would vary from $20 \times \frac{2}{3}$ to $20 \times \frac{1}{2}$, *i.e.*, from 16 to 10 tons/in.^{2}, as the case may be.

Digitized by Google

This working pressure, or normal chamber pressure, is that pressure which should not be exceeded by the ordinary service charge, and in the case of cordite the temperature of the charge is fixed at 80° F. It might be called the specification pressure.

The actual pressure which a charge does produce, as ascertained by means of the crusher gauge and coppers, is frequently below the working pressure, and is dependent on such things as wear of the gun, temperature of charge, &c.

An example is now worked out.

In a 6-inch B.L. gun

$$r_0 = 4,$$
$$r_1 = 5{\cdot}6,$$
$$r_2 = 8{\cdot}7,$$
$$r_3 = 11{\cdot}8.$$

Find all the Firing, Powder, and Initial Stresses.

Starting with firing pressures,

$$t_0 = 15; \qquad r_0^2 = 16,$$
$$t_1 = 18; \qquad r_1^2 = 31{\cdot}36,$$
$$t_2 = 18; \qquad r_2^2 = 75{\cdot}69,$$
$$r_3^2 = 139{\cdot}24.$$

Also $p_3 = 0$, hence for the outer tube,

$$t_2 = 18 = \frac{a}{r_2^2} + b,$$

$$p_3 = 0 = \frac{a}{r_3^2} - b.$$

Solving this, and making use of the gunmaker's formula (see p. 158)

$$p_2 = \frac{r_3^2 - r_2^2}{r_3^2 + r_2^2}(t_2 + p_3) + p_3.$$

So that, applying the formula for each tube or hoop,

$p_3 =$

$$p_2 = \frac{r_3^2 - r_2^2}{r_3^2 + r_2^2}(18 + 0) + 0 = \frac{63{\cdot}55}{214{\cdot}93}\,18 = 5{\cdot}32 \quad \text{(slide rule)}$$

$$p_1 = \frac{r_2^2 - r_1^2}{r_2^2 + r_1^2}(t_1 + p_2) + p_2 = \frac{44{\cdot}33}{107{\cdot}05}(18 + 5{\cdot}32) + 5{\cdot}32$$
$$= 9{\cdot}68 + 5{\cdot}32 = 15{\cdot}0$$

$$p_0 = \frac{r_1^2 - r_0^2}{r_1^2 + r_0^2}(t_0 + p_1) + p_1 = \frac{15{\cdot}36}{47{\cdot}36}(15 + 15) + 15$$
$$= 9{\cdot}74 + 15 = 24{\cdot}74.$$

The hoop tensions are found at once from formula

$$t'_n - p_n = t_{n-1} - p_{n-1}.$$

Digitized by Google

Since in the n^{th} hoop

$$t'_n = \frac{a}{r_n^2} + b,$$

$$\therefore t'_n - p_n = 2b.$$

$$p_n = \frac{a}{r_n} - b,$$

also,

$$t_{n-1} = \frac{a}{r^2_{n-1}} + b,$$

$$\therefore t_{n-1} - p_{n-1} = 2b.$$

$$p_{n-1} = \frac{a}{r^2_{n-1}} - b,$$

Applying this, we have

$$\text{Jacket} \begin{cases} t'_3 = (t_2 - p_2) + p_3 = 18 - 5{\cdot}32 + 0 = 12{\cdot}68, \\ t_2 = 18, \end{cases}$$

$$\text{Breech-piece} \begin{cases} t'_2 = (t_1 - p_1) + p_2 = 18 - 15 + 5{\cdot}32 = 8{\cdot}32, \\ t_1 = 18, \end{cases}$$

$$\text{Tube} \begin{cases} t'_1 = (t_0 - p_0) + p_1 = 15 - 24{\cdot}74 + 15 = 5{\cdot}26, \\ t_0 = 15. \end{cases}$$

Powder Stress: P, T.

The maximum allowable pressure has been found to be 24·74 tons/in.^{2}, this therefore is the maximum powder pressure in the interior of the bore.

$$\therefore P_0 = 24{\cdot}74.$$

To obtain the powder stresses at other parts of the gun, we treat the whole gun as one homogeneous mass of internal radius r_0 and external radius r_3.

$$P_0 = 24{\cdot}74 = \frac{a}{r_0^2} - b,$$

$$P_3 = 0 = \frac{a}{r_3^2} - b,$$

at any point

$$P = \frac{a}{r^2} - b,$$

$$T = \frac{a}{r^2} + b,$$

and a, b are the same constants throughout tube, breech-piece, and jacket.

Solving the equations, we have

$$a = \frac{r_0^2 r_3^2}{r_3^2 - r_0^2} p_0; \quad b = \frac{r_0^2}{r_3^2 - r_0^2} p_0.$$

$$\therefore P = \frac{r_0^2}{r_3^2 - r_0^2}\left(\frac{r_3^2}{r^2} - 1\right) = \frac{r_0^2}{r^2} \cdot \frac{r_3^2 - r^2}{r_3^2 - r_0^2} p_0,$$

$$T = \frac{r_0^2}{r_3^2 - r_0^2}\left(\frac{r_3^2}{r^2} + 1\right) = \frac{r_0^2}{r^2} \cdot \frac{r_3^2 + r^2}{r_3^2 - r_0^2} p_0.$$

$$\therefore P_0 = 24{\cdot}74,$$

$$P_1 = \frac{16}{31{\cdot}36} \cdot \frac{139{\cdot}24 - 31{\cdot}36}{139{\cdot}24 - 16} 24{\cdot}74 = \frac{16}{31{\cdot}36} \cdot \frac{107{\cdot}88}{123{\cdot}24} 24{\cdot}74 = 11{\cdot}1,$$

$$P_2 = \frac{16}{75{\cdot}69} \cdot \frac{139{\cdot}24 - 75{\cdot}69}{123{\cdot}24} 24{\cdot}74 = \frac{16}{75{\cdot}69} \cdot \frac{63{\cdot}55}{123{\cdot}24} 24{\cdot}74 = 2{\cdot}7,$$

$$P_3 = 0.$$

$$T_0 = \frac{16}{16} \cdot \frac{139{\cdot}24 + 16}{139{\cdot}24 - 16} \cdot 24{\cdot}74 = \frac{155{\cdot}24}{123{\cdot}24} 24{\cdot}74 = 31{\cdot}2,$$

$$T_1 = (t_0 - p_0) + p_1 = 31{\cdot}2 - 24{\cdot}74 + 11{\cdot}1 = 17{\cdot}56,$$

$$T_2 = (t_0 - p_0) + p_2 = 6{\cdot}46 + 2{\cdot}7 = 9{\cdot}16,$$

$$T_3 = (t_0 - p_0) + p_3 = 6{\cdot}46.$$

Initial Stress: (p), (t).

These are got by subtracting powder from firing stresses.

$$(p_0) = p_0 - P_0 = 24{\cdot}74 - 24{\cdot}74 = 0,$$
$$(p_1) = p_1 - P_1 = 15 - 11{\cdot}1 = 3{\cdot}9,$$
$$(p_2) = p_2 - P_2 = 5{\cdot}32 - 2{\cdot}7 = 2{\cdot}62,$$
$$(p_3) = p_3 - P_3 = 0 - 0 = 0,$$

Tube
$$(t_0) = t_0 - T_0 = 15 - 31{\cdot}2 = -16{\cdot}2,$$
$$(t'_1) = t'_1 - T_1 = 5{\cdot}26 - 17{\cdot}56 = -12{\cdot}30,$$

Breech-piece
$$(t_1) = t_1 - T_1 = 18 - 17{\cdot}56 = 0{\cdot}44,$$
$$(t'_2) = t'_2 - T_2 = 8{\cdot}32 - 9{\cdot}16 = -0{\cdot}84.$$

Jacket
$$(t_2) = t_2 - T_2 = 18 - 9{\cdot}16 = 8{\cdot}84,$$
$$(t'_3) = t'_3 - T_3 = 12{\cdot}68 - 6{\cdot}46 = 6{\cdot}22.$$

The figs. 8 and 9 show the various stresses for this 6-inch gun to one place of decimals. A similar procedure will apply for a gun built up of four or more parts.

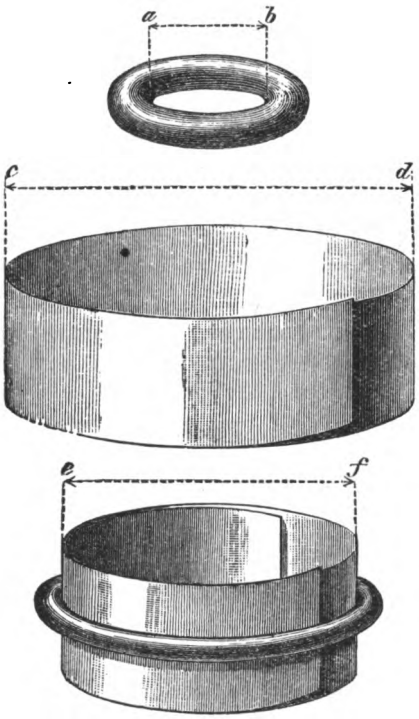
Fig. 8.

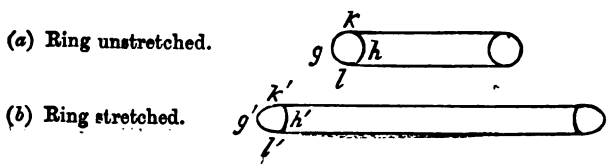
Digitized by Google

Fig. 9.

A simple illustration of initial stress may be given by means of an india-rubber ring (fig. 10) of interior diameter *ab*, and a loose cardboard roll of greater diameter, *cd*. If the former is stretched, put over the latter, and left to itself, contraction of both will take place to some diameter *ef*, intermediate between *ab* and *cd*.

Fig. 10.





Digitized by Google

A state of stress is thus produced between the ring and the roll, the one being larger and the other smaller than at first, and each having its elastic tendency to return to its own original dimensions resisted by the reaction of the other; a normal or radial pressure acts at the surface of contact, which causes a *lengthening* of the india-rubber ring circumferentially, indicating *hoop tension;* and this same normal pressure makes the cardboard roll *smaller* in circumference, indicating *hoop pressure.* The cardboard roll is stronger than before, to resist an interior normal pressure, while the ring is weaker, but still it may be strong enough for the tension which will come upon it; and the stress in the materials is more nearly equalised.

If fig. 10 represents a section of the india-rubber ring (*a*) in its unstretched state; (*b*) when it is expanded over the cardboard roll, we note that although the ring becomes larger in diameter when it is stretched, and slightly changes in volume, owing to its elasticity, it becomes thinner in section, both in the direction of the radius and of the axis of the roll, *i.e.*, gh contracts to $g'h'$, and kl contracts to $k'l'$.

Case of a Cracked Tube.

If the A tube is cracked through longitudinally on both sides, its tensile strength is nil and the gun will not stand the same strain as before.

Thus in the 6-inch gun worked out, from p. we have the firing radial pressures,

$$p_1 = 15; \quad p_0 = 24{\cdot}74;$$

but with the A tube cracked p_0 will not be so large: the two outer tubes being undamaged we get as before

$$p_1 = 15.$$

Although the tensile strength of the A tube is nil, yet it serves to diminish the surface over which the powder pressure acts, and therefore

$$p_0 = p_1 \frac{r_1}{r_0}.$$

This may be seen also from considering the equilibrium of the A tube; the forces acting on this tube are radial pressures,

$p_1 = 15$ tons/in.^{2} over a surface $2\pi r_0$, acting inwards,

p_0 over a surface $2\pi r_0$, acting outwards,

therefore

$$(2\pi r_1)\, p_1 = (2\pi r_0)\, p_0,$$

$$p_0 = p_1 \frac{r_1}{r_0} \quad \ldots\ldots\ldots \quad \text{(XIV)},$$

$$= 15 \cdot \frac{5{\cdot}6}{4} = 21{\cdot}0.$$

So that our maximum allowable pressure has been reduced from 24·74 to 21·0 tons/in.^{2}, due to the A tube being cracked.

Liners.

In the case of liners, no strength is accredited; for, being put in without shrinkage, they are taken as so much packing, and their effect as regards calculation of strength might be ignored but for the fact that they distribute the strain to a larger area. Of course, here, as in the case of shrinkage friction, with reference to longitudinal strength, any circumferential strength derived from the liner will be in addition to that calculated for.

Supposing the gun to have been designed for, and constructed originally with, a liner, then if p_0 represents the internal pressure on the liner, and p that transmitted to the interior of the A tube, and r_0 and r_1 the respective radii, the formula is simply

$$p_0 = p\,\frac{r}{r_0} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad \text{(XV)},$$

the liner acting as if cracked or segmental.

THE STRAIN OF THE GUNS.

So far we have dealt only with the *stress* in the metal, but when the gunmaker wishes to set up a given pressure of shrinkage between two cylinders, he has to determine, by calculation or experiment, the slight amount by which, when cold, the external radius of one cylinder must exceed the internal radius of the next cylinder which is shrunk on it.

The outer cylinder is expanded by heat and slipped on, in order that the given initial pressure may be set up on the cooling of the outer cylinder; and this, too, when other cylinders are shrunk on afterwards.

We must therefore determine the strain and deformation set up in a given cylinder due to given applied pressure, and thus we require the equations giving the strain due to given applied stress when the co-efficients of elasticity of the metal are known.

The mathematical steps leading to the solution of this problem will be given in Part II; the general formula to be employed is

$$_mS_{m+1} = (t_m) - (t'_m)\,\frac{2r_m}{M} \quad . \quad . \quad . \quad . \quad . \quad \text{(XVI)}.$$

Here any value from 0 upwards can be given to m so as to obtain $_mS_{m+1}$, which is either the contraction of the bore for $m = 0$, or the shrinkage between hoops, or the extension of the outside layer, in inches, at any radius of r_m inches; τ and τ' are the usual initial tensions, M the modulus of elasticity, taken usually as 12,500 tons/in^2 for gun steel.

A numerical example will show the use of the formula.

Calculating by the formula above, the shrinkage of the 6-inch gun, with the values of (t) shown in figure on p. , and commencing from the interior, we find that

$$_0S_1 = (t_0) \times 2r_0 \div M = 16{\cdot}2 \times 8 \div 12{,}500 = 0{\cdot}0103 \text{ inch},$$

said practically to be 10-thousandths of an inch; this is the final contraction of the bore, or the amount by which its diameter must be turned larger at first, in order that its diameter may be 8 inches.

Digitized by Google

$$_1S_2 = [(t_1) - (t'_2)] \times 2r_1 \div M = \{\cdot4 - (-12\cdot3)\} \times 11\cdot2 \div 12{,}500 = 0\cdot0112 \text{ inch},$$

that is, the exterior of the A tube should be made 11-thousandths of an inch larger than the interior of the breech-piece.

$$_2S_3 = [(t_2) - (t'_2)] \times 2r_2 \div M = 9\cdot64 \times 17\cdot4 \div 12{,}500 = 0\cdot0135 \text{ inch},$$

or after the breech-piece has been shrunk on, its outside (now expanded) diameter should be 13-thousandths of an inch larger than the interior of the jacket.

$$_3S_4 = (t'_3) \times 2r_3 \div M = 6\cdot2 \times 23\cdot6 \div 12{,}500 = 0\cdot012 \text{ inch},$$

the elongation of the external diameter of the jacket up to its final diameter of 23·6 inches.

The values of (t_m) and (t'_m) are the *initial* stresses, and as the powder pressure P_m at r_m increases them by equal amounts to t_m and t'_m, the firing stresses, their difference is unaltered, so that

$$(t_m) - (t'_m) = t_m - t'_m;$$

hence so long as we are considering the shrinkage between hoops, we can calculate it either from the firing or initial stresses: for example, as above

$$_1S_2 = (t_1 - t'_1) \times 2r_1 \div M = (18 - 5\cdot3) \times 11\cdot2 \div 12{,}500 = 0\cdot0112$$

as before.

With several layers of metal the addition of each part that is shrunk on, modifies the initial stresses previously existing.

FIG. 11—SHRINKAGE EXAGGERATED 50 TIMES.

Scale, $\frac{1}{3}$.

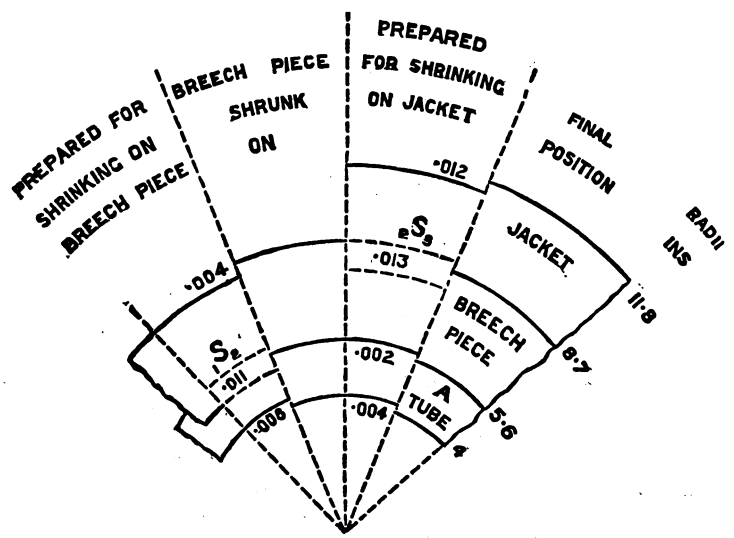

Fig. 11 shows the shrinkage (exaggerated for clearness) of the different parts, and the intermediate and final arrangements when a breech-piece and jacket are successively shrunk on, over the chamber portion of the A tube of a 6-inch B.L. gun.

Digitized by Google

WIRE GUN CONSTRUCTION.

In fig. 8, which gives the firing stresses of a 6-inch gun, it is seen from the curves of circumferential tension $t_0t'_1$, $t_1t'_2$, $t_2t'_3$ that only the *inner* fibre of each layer of metal is doing its full share of resistance when the gun is fired.

Great economy of material would be effected if we could make all the circumferential fibres take up a full uniform tension (say of 18 tons per square inch) on firing; but to secure this condition only approximately, the number of layers of metal would have to be largely increased, and the cost, complication, and time of manufacture of a gun would be enormous.

But by adopting Mr. J. A. Longridge's plan of strengthening the tube by steel wire, wound round with appropriately varying tension, we are able to make the curve of circumferential firing tension $t_1t'_2$ a straight line for a given powder pressure (fig. 13), and now all parts of the wire coil are equally strained under the interior pressure, and take an equal share in the resistance.

For full theoretical investigation of this subject, see Mr. Longridge's "Treatise on the Application of Wire to the Construction of Ordnance" (1884), and a paper of 1887, "Further Investigations regarding Wire Gun Construction," also a Work by Lieutenant G. Moch, "Les Canons à Fils d'Acier."

By winding on many layers of steel wire on an A tube, we can get every layer of the wire coil to do its full share of resistance when the gun is fired, and so greatly strengthen the gun, provided each layer of wire is wound on with a properly adjusted tension.

A steel hoop shrunk over an A tube must not be subjected to a firing tension of over 18 tons/in.^{2}, whereas steel wire can safely be subjected to a tension of 50 tons/in.^{2}, therefore we have not only a much strengthened gun by using steel wire, but there is a considerable saving in the weight of metal to be used.

In a gun which has steel hoops shrunk on, the curve of radial pressure for each hoop is given by

$$p = \frac{a}{r^2} - b,$$

and the circumferential tension by

$$t = \frac{a}{r^2} + b,$$

where a and b are constants to be determined for each hoop or tube.

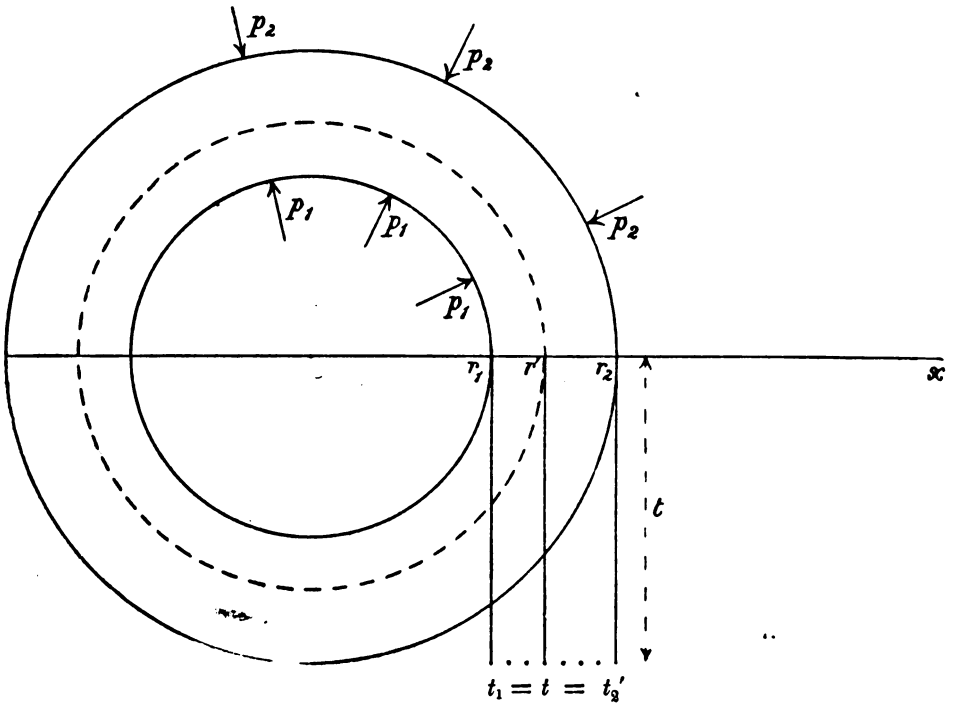
These equations do not hold good for the firing stresses in a wire coil which has been wound round on an A tube; because the winding tension of each layer of wire has been adjusted so that the firing tension may be the same throughout the coil.

The jacket is required for the protection of the wire from damage and to provide the necessary longitudinal strength; it is fitted over the wire without any appreciable shrinkage.

When the gun is at rest the jacket will be free from stress, but when the gun is fired we may suppose the stress in it to be the powder stress only, on the assumption that the gun behaves as if homogeneous.

Digitized by Google

Fig. 12.



In fig. 12, let r_1 and r_2 be the internal and external radii of the wire coil, and let a powder pressure p_0 be applied so that the radial firing pressures at r_1, r_2 be p_1, p_2 respectively, and the tension throughout $= t$, so that

$$t_1 = t'_2 = t.$$

To find the radial pressure p at any point r in the wire coil.

Consider the equilibrium of the portion of the wire between r_1 and r; we have

$$p_1 r_1 = pr + t\,(r - r_1) \quad . \quad . \quad . \quad . \quad . \quad \text{(XVII)}.$$

If the portion of wire coil between r and r_2 be considered, we have

$$pr = p_2 r_2 + t\,(r_2 - r),$$

and for the whole coil from r_1 to r_2,

$$p_1 r_1 = p_2 r_2 + t\,(r_2 - r_1).$$

From these last two equations we have, by subtraction,

$$p_1 r_1 - pr = t\,(r - r_1),$$

or

$$p_1 r_1 = pr + t\,(r - r_1),$$

which is equation (XVII) over again.

From equation (XVII), by writing x for r and y for p,

$$p_1 r_1 = xy + t\,(x - r_1),$$

or

$$x\,(y + t) = (p_1 + t)\,r_1 = \text{const.} = \text{A},$$

Digitized by Google

and moving the axis of x parallel to itself at a distance t, this reduces to

$$xy = \text{const.}$$

This is the equation of a rectangular hyperbola.
From equation (XVII) we have

$$(p + t)\, r = p_1 r_1 + t r_1 = \text{const., say A,}$$

$$\therefore p + t = \frac{A}{r} \quad . \quad . \quad . \quad . \quad . \quad . \quad \text{(XVIII).}$$

This gives a convenient equation to find the radial pressure at any point in the wire coil.
In the A tube and jacket only, the equations

$$p = \frac{a}{r^2} - b,$$

$$t = \frac{a}{r^2} + b,$$

hold good to find the stress at any point.
In wire guns the limits which are usually laid down are:—

1st. That the maximum circumferential tension in the A tube on firing is 15 tons/in.^{2}, so that $t_0 = 15$.

2nd. That the crushing circumferential pressure (or negative tension) of the steel in the tube in a state of repose be not greater than 26 tons/ins.^{2}.

This crushing pressure is caused by the wire which is wound on the A tube at great tension, tending to compress tightly the tube; we have, therefore

$$(t_0) = -26.$$

This amount (26) may be reduced in parts of the gun where the the wire coil is thinner.
In wire guns at present, the wire is wound on to the A tube after the inner A tube has been fitted into it, and so at first the A tube is not fully compressed, which gives an advantage in the first life of the gun, but on boring out for lining, then the full compression takes place, and the advantage referred to is lost.
So also in the 6-inch Q.F., Mark II, where the I-B tube is shrunk on to the A tube under the wire, the metal under the wire coil should be treated as homogeneous, because in boring out for lining the A tube will be compressed, and the advantage of the shrinkage lost.
An example is now worked out fully. In the 9·2-inch B.L. Mark X, the dimensions across the middle of the powder chamber are

$r_0 =$	6·5 inches	then	$r_0^2 =$ 42·25.
$r_1 =$	11·0 ,,		$r_1^2 =$ 121·0.
$r_2 =$	13·76 ,,		$r_2^2 =$ 189·3.
$r_3 =$	16·5 ,,		$r_3^2 =$ 272·3.

Digitized by Google

We have to start with

t_0 shall not exceed 15 tons/in.^{2}

(t_0) " " $= 26$

Take

$$t_0 = 15,$$
$$(t_0) = -26.$$

Then, since firing tension = powder tension + initial tension,

$$t_0 = T_0 + (t_0)$$
$$\therefore T_0 = t_0 - (t_0) = 15 - (-26) = 41$$

The maximum powder tension is therefore 41. Treating the whole gun (A tube, wire coil and jacket) as one homogeneous mass for the powder stress we have

$$P_3 = 0 = \frac{a}{r_3^2} - b,$$

$$T_0 = 41 = \frac{a}{r_0^2} + b.$$

To get powder pressures P_0, P_1, P_2:

$$P_3 + T_0 = a\left(\frac{1}{r_3^2} + \frac{1}{r_0^2}\right),$$

$$\therefore a = \frac{r_3^2 r_0^2}{r_3^2 + r_0^2} T_0, \text{ because } P_3 = 0,$$

$$b = \frac{a}{r_3^2} = \frac{r_0^2}{r_3^2 + r_0^2} T_0,$$

$$\therefore P = \frac{a}{r^2} - b = \frac{r_0^2}{r_3^2 + r_0^2}\left(\frac{r_3^2}{r^2} - 1\right) T_0$$

$$= \frac{r_0^2}{r^2} \cdot \frac{r_3^2 - r^2}{r_3^2 + r_0^2} T_0.$$

$$P_0 = \frac{r_3^2 - r_0^2}{r_3^2 + r_0^2} 41 = \frac{272{\cdot}3 - 42{\cdot}25}{272{\cdot}3 + 42{\cdot}25} 41 = \frac{230{\cdot}05}{314{\cdot}55} 41 = 30$$

(by slide rule),

$$P_1 = \frac{r_0^2}{r_1^2} \cdot \frac{r_3^2 - r_1^2}{r_3^2 + r_0^2} 41 = \frac{42{\cdot}25}{121} \cdot \frac{151{\cdot}3}{314{\cdot}55} 41 = 6{\cdot}88,$$

$$P_2 = \frac{r_0^2}{r_2^2} \cdot \frac{r_3^2 - r_2^2}{r_3^2 + r_0^2} 41 = \frac{42{\cdot}25}{189{\cdot}3} \cdot \frac{83{\cdot}0}{314{\cdot}515} 41 = 2{\cdot}43,$$

$$P_3 = 0.$$

Again $T_3 - P_3 = 2b = T_2 - P_2 = T_1 - P_1 = T_0 - P_0$,

$$\therefore T_3 = (T_0 - P_0) + P_3 = (41 - 30) + 0 = 11,$$
$$T_2 = (T_0 - P_0) + P_2 = 11 + 2{\cdot}43 = 13{\cdot}43,$$
$$T_1 = (T_0 - P_0) + P_1 = 11 + 6{\cdot}88 = 17{\cdot}88.$$

Digitized by Google

We have now found all the powder pressures, to one place of decimals; these are

$$P_0 = 30, \qquad T_0 = 41,$$
$$P_1 = 6{\cdot}9, \qquad T_1 = 17{\cdot}9,$$
$$P_2 = 2{\cdot}4, \qquad T_2 = 13{\cdot}4,$$
$$P_3 = 0, \qquad T_3 = 11.$$

Firing Stress p, t.

The maximum powder pressure P_0 has been found, and in firing this is also the maximum pressure inside the bore,

$$\therefore\ p_0 = P_0 = 30.$$

In the A tube (which includes the inner A tube, both tubes being regarded as homogeneous)

$$p_0 = \frac{r_1^2 - r_0^2}{r_1^2 + r_0^2}(t_0 + p_1) + p_1 \text{ (gun maker's formula)},$$

$$30 = \frac{78{\cdot}75}{163{\cdot}25}(15 + p_1) + p_1 = {\cdot}4825(15 + p_1) + p_1,$$

$$\therefore\ 1{\cdot}4825\, p_1 = 30 - 7{\cdot}237 = 22{\cdot}76,$$

$$\therefore\ p_1 = 15{\cdot}34.$$

So

$$t'_1 = (t_0 - p_0) + p_1(15 - 30{\cdot}0) + 15{\cdot}34 = 0{\cdot}34.$$

In the wire coil, each layer of wire is wound on so that on firing the tension is the same, so that $t_1 = t'_2 = t$ throughout. Then, from considering the equilibrium of the whole coil,

$$p_1 r_1 = p_2 r_2 + t(r_2 - r_1),$$

$$\therefore\ t = \frac{p_1 r_1 - p_2 r_2}{r_2 - r_1} = \frac{168{\cdot}74 - 33{\cdot}02}{2{\cdot}76} = \frac{135{\cdot}72}{2{\cdot}76}$$

$$= 49{\cdot}15.$$

$$\therefore\ t_1 = t'_2 = t = 49{\cdot}15.$$

Since there are no initial stresses in the jacket

$$p_2 = P_2 = 2{\cdot}4,$$
$$p_3 = P_3 = 0,$$
$$t_2 = T_2 = 13{\cdot}4,$$
$$t'_3 = T_3 = 11.$$

Weller & Graham, Ltd. Litho London

Thus all the firing stresses are found; we have to one place of decimals,

$$\text{A tube}\begin{cases} p_0 = 30 & t_0 = 15 \\ p_1 = 15{\cdot}3 & t'_1 = 0{\cdot}3, \end{cases}$$

$$\text{wire coil} \qquad t_1 = t'_2 = t = 49{\cdot}1,$$

$$\text{jacket}\begin{cases} p_2 = 2{\cdot}4 & t_2 = 13{\cdot}4 \\ p_3 = 0 & t'_3 = 11. \end{cases}$$

Initial Stresses (p), (t).

$$\begin{aligned}
(p_0) &= p_0 - P_0 = 30 - 30 = 0 \\
(p_1) &= p_1 - P_1 = 15{\cdot}3 - 6{\cdot}9 = 8{\cdot}4 \\
(p_2) &= p_2 - P_2 = \qquad\quad = 0 \\
(p_3) &= p_3 - P_3 = \qquad\quad = 0 \\
(t_0) &= t_0 - T_0 = 15 - 41 = -26 \\
(t'_1) &= t'_1 - T_1 = 0{\cdot}3 - 17{\cdot}9 = -17{\cdot}6 \\
(t_1) &= t_1 - T_1 = 49{\cdot}1 - 17{\cdot}9 = 31{\cdot}2 \\
(t'_2) &= t'_2 - T_2 = 49{\cdot}1 - 13{\cdot}4 = 35{\cdot}7 \\
(t_2) &= t_2 - T_2 = 13{\cdot}4 - 13{\cdot}4 = 0 \\
(t'_3) &= t'_3 - T_3 = 11 - 11 = 0.
\end{aligned}$$

Figs. 14 and 15 show the various stresses to scale.

From the figure giving the firing stresses, it will be seen that since the outer edge of the A tube has practically no circumferential tension ($t'_1 = 0{\cdot}3$) on firing, that the chief stress on firing is thrown upon the wire.

Fig. 13.

Fig. 14.

Winding Tension.

Fig. 14 shows the curve (t_1) (t) (t'_2) of initial tension of the wire; it is necessary now to find out the tension with which each layer of wire must be wound on the tube so that when the whole wire coil is completed, we shall have obtained the correct initial tension of the wire.

Fig. 15.

In fig. 15 the shaded portion represents the wire coil, and the dotted circle has a radius r. Let θ be the winding tension for this layer of wire, then the outer layers of wire will compress it, and so diminish its winding on tension by an amount $(t)^*$; what is required is that $\theta + (t)^*$ shall equal the correct initial tension of this layer of wire, that is, we must have

$$\theta + (t)^* = (t) \quad . \quad . \quad . \quad . \quad . \quad . \quad \text{(XIX)},$$

$(t)^*$ will be shown to be negative in value.

Suppose the radial pressure at r due to the outer layers is (p), then we want to find what compressions (*i.e.*, negative tension) are produced by (p).

Treating the gun from r_0 to r as homogeneous, we have

$$(p) = \frac{a}{r} - b,$$

$$(p_0) = 0 = \frac{a}{r_0^2} - b,$$

$$(t)^* = \frac{a}{r^2} + b.$$

Whence

$$a = -\frac{r_0^2 r^2}{r^2 - r_0^2}(p),$$

$$b = -\frac{r^2}{r^2 - r_0^2}(p),$$

$$\therefore (t)^* = -\frac{r^2 + r_0^2}{r^2 - r_0^2}(p).$$

$(t)^*$ is negative, denoting a compression.

From (19)

$$\theta = (t) - (t)^*$$

$$= (t) + \frac{r^2 + r_0^2}{r_2 - r_0^2}(p) \quad \ldots\ldots \quad \text{(XX)}.$$

In this

$$(t) = t - \mathrm{T}$$

$$= t - \frac{r_0^2}{r^2} \cdot \frac{r_3^2 + r^2}{r_3^2 - r_0^2} p_0,$$

also

$$(p) = p - \mathrm{P} = p - \frac{r_0^2}{r^2} \cdot \frac{r_3^2 - r^2}{r_3^2 - r_0^2} p_0.$$

Lastly, from consideration of the equilibrium of the wire coil from r to r_2 (or from r_1 to r),

$$pr = p_2 r_2 + t(r_2 - r),$$

whence

$$p = \frac{p_2 r_2 + t(r_2 - r)}{r},$$

$$\therefore (p) = \frac{p_2 r_2 + t(r_2 - r)}{r} - \frac{r_0^2}{r^2} \cdot \frac{r_3^2 - r^2}{r_3^2 - r_0^2} p_0. \quad \text{(XXI)}.$$

Substituting these values of (t) and (p) in (20) we have

$$\theta = t - \frac{r_0^2}{r^2} \cdot \frac{r_3^2 + r^2}{r_3^2 - r_0^2} p_0$$

$$+ \left[\frac{p_2 r_2 + t(r_2 - r)}{r} - \frac{r_0^2}{r^2} \cdot \frac{r_3^2 - r^2}{r_3^2 - r_0^2} p_0\right] \frac{r^2 + r_0^2}{r^2 - r_0^2}.$$

Digitized by Google

Coefficient of p_0 is

$$-\frac{r_0^2}{r^2}\cdot\frac{r_3^2+r^2}{r_3^2-r_0^2}-\frac{r_0^2}{r^2}\cdot\frac{(r_3^2-r^2)(r^2+r_0^2)}{(r_3^2-r_0^2)(r^2-r_0^2)}$$

$$=-\frac{r_0^2}{r^2}\cdot\frac{(r_3^2+r^2)(r^2-r_0^2)+(r_3^2-r^2)(r^2+r_0^2)}{(r_3^2-r_0^2)(r^2-r_0^2)},$$

$$=-\frac{r_0^2}{r^2}\cdot\frac{2r_3^2r^2-2r^2r_0^2}{(r_3^2-r_0^2)(r^2-r_0^2)},$$

$$=-\frac{r_0^2}{r^2}\cdot\frac{2r^2(r_3^2-r_0^2)}{(r_3^2-r_0^2)(r^2-r_0^2)},$$

$$=-\frac{2r_0^2}{r^2-r_0^2}.$$

Coefficient of t

$$=1+\frac{r_2-r}{r}\cdot\frac{r^2+r_0^2}{r^2-r_0^2},$$

$$=\frac{r^3-rr_0^2+r^2r_2-r^3+r_2r_0^2-rr_0^2}{r(r^2-r_0^2)},$$

$$=-\frac{2rr_0^2+r_2(r^2+r_0^2)}{r(r^2-r_0^2)},$$

$$=-\frac{2r_0^2}{r^2-r_0^2}+\frac{r_2}{r}\cdot\frac{r^2+r_0^2}{r^2-r_0^2}.$$

$$\therefore\theta=(t+p_2)\frac{r_2}{r}\cdot\frac{r^2+r_0^2}{r^2-r_0^2}-\frac{2r_0^2}{r^2-r_0^2}(t+p_0) \quad . \quad \text{(XXII)},$$

resolving into partial fractions

$$\frac{r_2}{r}\cdot\frac{r^2+r_0^2}{r^2-r_0^2}=-\frac{r_2}{r}+\frac{r_2}{r-r_0}+\frac{r_2}{r-r_0},$$

so

$$\frac{2r_0^2}{r^2-r_0^2}=\frac{r_0}{r-r_0}-\frac{r_0}{r+r_0}.$$

$$\therefore\theta=(t+p_2)\left(-\frac{r_2}{r}+\frac{r_2}{r-r_0}+\frac{r_2}{r-r_0}\right)-(t+p_0)\left(\frac{r_0}{r-r_0}-\frac{r_0}{r+r_0}\right),$$

$$=-\frac{(t+p_2)r_2}{r}+\frac{(t+p_2)r_2-(t+p_0)r_0}{r-r_0}+\frac{(t+p_2)r_2+(t+p_0)r_0}{r+r_0}$$

$$=\frac{A}{r}+\frac{B}{r-r_0}+\frac{C}{r+r_0} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad \text{(XXIII)},$$

where

$$A=-(t+p_2)r_2,$$

$$B=(t+p_2)r_2-(t+p_0)r_0,$$

$$C=(t+p_2)r_2+(t+p_0)r_0.$$

Digitized by Google

Formula (XXIII) is very convenient for calculating θ for any value of r, since A, B, and C are the same for each layer.

The winding tension of the last layer of wire must be the same as the tension in repose, so that at r_2,

$$\theta_2 = (t'_2) = 35{\cdot}7 \text{ tons/in}^2,$$

since the jacket is put on without shrinking, and therefore $(p_2) = \theta$ in formula (XX).

The winding on tension of the inner or first layer can be obtained directly from (XX), thus

$$\theta_1 = (t_1) + \frac{r_1^2 + r_0^2}{r_1^2 - r_0^2}(p_1),$$

and (t_1), (p_1) have already been found,

$$\therefore \theta_1 = 31{\cdot}2 + \frac{(11)^2 - (6{\cdot}5)^2}{(11)^2 + (6{\cdot}5)^2} 8{\cdot}4,$$

$$= 48{\cdot}7 \text{ tons/in.}^2.$$

This value could have been obtained equally well from (XXIII)

$$\theta_1 = \frac{A}{r_1} + \frac{B}{r_1 - r_0} + \frac{C}{r_1 + r_0}.$$

The Longitudinal Tension in the Gun.

Practically it is usual to take the longitudinal tension as uniform across a cross section and as due to the powder pressure in the bore, treated as a closed vessel, closed at one end by the breech-screw, and at the other by the shot.

Thus supposing a breech-screw to gear into an A tube of which the internal radius is r_0 and the external radius of the gun is r_2, taking P_0 as the powder pressure, the average value R of the longitudinal tension will be found as follows:—The pressure multiplied by the sectional area of the chamber is resisted by a cross section of the metal subjected to longitudinal tension (according to the design of the gun); for equilibrium, these must be equal, therefore in this case

$$P_0 \pi r_0^2 = R\pi (r_2^2 - r_0^2)$$

$$R = P_0 \frac{r_0^2}{r_2^2 - r_0^2} \text{ tons/in.}^2.$$

In all steel guns of modern construction the breech-screw gears into the layer of metal above the A tube; in smaller guns direct; in heavier pieces of the most recent construction by means of a steel bush; the inner tube is thus relieved of longitudinal stress at the breech. For a gun consisting of a tube and jacket only, the formula would then become

$$R = P_0 \frac{r_0^2}{r_2^2 - r_1^2}.$$

Considering the longitudinal strength of the 6-inch B.L. gun,

$$P_0 = \frac{r_2^2 - r_1^2}{r_0^2} R;$$

with the given numerical values and putting $R = R_1 = 18$ gives

Digitized by Google

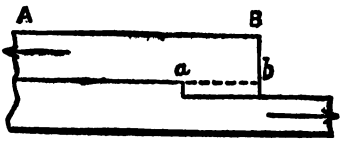
$P_0 = 121$, and dividing this by a normal pressure of 17 tons, we get a longitudinal factor of safety $= 7{\cdot}1$.

Practically the longitudinal strength is considered separately from the circumferential, and is specially provided for by shoulder, of which the *resistance to shearing* constitutes the longitudinal strength as calculated. No account is taken of frictional grip due to shrinkage, for it is considered as extremely probable that at the critical moment this becomes loosened by the elasticity of the different layers asserting itself more rapidly towards the interior as soon as the highest pressure has passed, while there is still a considerable longitudinal stress.

It is considered inadvisable to rely upon shrinkage in any way for longitudinal strength, and, consequently, any strength in this direction derived from the frictional grip will be in addition to the calculated strength.

The strain sustained by a shoulder is taken as a purely shearing one, and the strength of a shoulder is consequently dependent on its length; shearing strength, like resistance to tension, being directly proportional to the extent of surface where separation would take place. The strength is also here taken to be the same (in tons per square inch), which, if not strictly true, is rather in favour of the shearing strength.

The calculation, therefore, of length of shoulder for a given hoop is simple. For if AB is the supporting hoop, of internal and external



radii r_1, r_2 and length of shoulder ab ($= l$ say), it is only necessary to make the cylindrical area of ab = the annular sectional area of the hoop, or—

$$\pi(r_2^2 - r_1^2) = 2\pi r_1 l,$$

whence,

$$l = \frac{r_2^2 - r_1^2}{2r_1}.$$

The actual longitudinal strength of this arrangement would appear to be—

$$\pi(r_2^2 - r_1^2)\ \mathrm{T},$$

or

$$2\pi r_1 l \mathrm{T},$$

T being the resistance to rupture by tension or shearing in tons per square inch of material where separation would take place.

Examples.

1. What is the maximum allowable pressure in the chamber (diam. 8 inches) of a 6-inch B.L. steel gun having an A tube $1\frac{1}{2}$ inches thick, breech-piece and jacket 3 inches each?

(*Answer*, 24 tons/in.^{2}.)

Digitized by Google

2. What is the maximum allowable chamber pressure in a steel gun having a chamber diameter 4 inches, and thickness of metal in A tube and jacket 1 and 2 inches respectively?

(*Answer*, 17·6 tons/in.².)

3. Calculate the initial stress of repose in a 5-inch B.L. steel gun having chamber diameter 6 inches, tube 2 inches, and jacket 4 inches thick?

(*Answer*, $(t_0) = -11{\cdot}25$; $(t'_1) = -7{\cdot}63$; $(t_1) = 6{\cdot}87$; $(t'_2) = 3.25$; $(p_1) = 3{\cdot}62$.)

4. What will be stress on firing of the gun in problem 3 if a charge giving 16 tons/in.² chamber pressure is used?

(*Answer*, $p_0 = 16$; $p_1 = 8{\cdot}1$; $t_0 = 8{\cdot}75$; $t_1 = 15{\cdot}35$; $t'_1 = 0{\cdot}85$; $t_2 = 7{\cdot}25$; $P_1 = 4{\cdot}48$; $T_0 = 20$; $T_1 = 8{\cdot}48$; $T'_2 = 4$.)

5. A gun of two layers of steel is to be designed to stand a maximum pressure in the chamber (diameter 5·8 inches) of 21 tons/in.², the tube being 2·1 inches thick; calculate what should be the external diameter of the gun.

(*Answer*, 17·372 inches.)

6. Calculate what the thickness of steel should be at two points on the chase of a light Q.F. gun of 3 inches calibre, where gas pressures of 5 and 4 tons/in.² respectively are expected. A factor of safety of 2 must be allowed, and the surface of the bore must not be strained to more than 15 tons/in.².

(*Answer*, 1·854 inches and 1·219 inches.)

7. The wire coil of a 4·7-inch quick-firing gun exerts an initial radial pressure on the A tube of 7·1 tons/in.²; calculate the state of initial hoop pressure of the latter, which is 1¼ inch thick, and has an internal diameter (at the centre of the cartridge chamber) of 5 inches.

(*Answer*, 18·46 tons/in.² at the outside.)
25·56 „ „ inside.)

8. At the commencement of the rifling in a 5-inch B.L. howitzer, the thickness of the jacket and A and B tubes is 1 inch. Calculate the maximum allowable gas pressure, and the skin circumferential tension on the outside of the jacket in repose.

Calculate the maximum pressure allowable when

(*a*) jacket is cracked;
(*b*) B tube is cracked;
(*c*) A tube cracked.

(*Answer*, $P_0 = 16{\cdot}7$, $(t'_3) = 5{\cdot}8$):
(*a*.) 10·70; (*b*.) 11·00; (*c*.) 12·50.

9. If the dimensions midway across the chamber of a 4·7-inch Q.F. Mark IV gun be $r_0 = 2{\cdot}5$, $r_1 = 4$, thickness of wire coil 1·5, thickness of jacket 2·0, show on diagrams to scale the complete firing, powder and initial stresses for a maximum allowable gas pressure.

10. What would be firing stresses in problem 9 if a charge giving 17 tons/in.² chamber pressure is used?

11. In the three following wire guns, compare the maximum allowable pressure in the chamber on firing, supposing that on the inner surface of the A tube the maximum allowable tension on firing is 15 tons/in.², and the maximum allowable compression at rest is 26 tons/in.²,

Digitized by Google

	Diameter of chamber.	Thickness of A tube.	Thickness of wire coil.	Thickness of jacket.
a ..	16	4·44	4·56	4

c ..	18	4·335	4·58	3·085

(*Answer*, (*a*.) 30·61 tons/in.²
(*b*.) 30·05 ,,
(*c*.) 28·28 ,, .)

12. Find the winding-on tension of the first and last layers of wire in the case of the gun in question 10*a*.
(*Answer*, 35·19; 22·68.)

13. Supposing the inner A tube (thickness 1·925 inch) of the gun in question 11*a* to be split, find the maximum allowable pressure in the chamber. (*Answer*, 28·1 tons/in.².)

14. Calculate the firing stress in the case of the gun given in question 10*b*, supposing that the service charge gave a maximum pressure of 15 tons/in.².
(*Answer*—

$t_0 = -5{\cdot}552$ $\quad t'_1 = -9{\cdot}095$
$t_1 = 27{\cdot}145$ $\quad t'_2 = 30{\cdot}475$
$t_2 = 6{\cdot}715$ $\quad t'_2 = 5{\cdot}448$.)

SECTION II.—THE RIFLING OF GUNS.

A gun is said to be rifled when the interior of the bore is cut into a number of spiral grooves, intended to engage in the projectile, and to give it a spin on leaving the muzzle.

In this manner the gun is enabled to fire an elongated projectile heavier than a spherical shot, and less influenced by the resistance of the air, so that the projectile ranges farther and hits harder and straighter; the spin imparted is sufficient to keep the shot moving point foremost, as otherwise the shot, if fired from a smooth bore, would soon set its axis across the line of motion, and the accuracy and range would be greatly diminished.

The requisite angle at which the grooves leave the muzzle is determined by the outside shape and proportions of the projectile, and by its interior density and distribution of material; but the grooves in passing from the breech to the muzzle may be made either—

(i) in a uniform twist,
or (ii) in an increasing twist.

In the uniform twist the form of the grooves is a uniform spiral or helix, so that, if traced on a sheet of paper which is wrapped on the interior of the bore, the curve becomes a straight line when the paper is developed, or laid out flat.

This can be illustrated by a sheet of paper wrapped round a pencil, the angle of the rifling being the angle between the axis of the pencil and the edge of the paper.

Digitized by Google

In the gaining twist the developed curve is one which becomes more and more inclined to the line of axis of the bore in passing from the breech to the muzzle, where the inclination β to the axis must be the same as in the uniform twist if the gun is required to fire the same projectile.

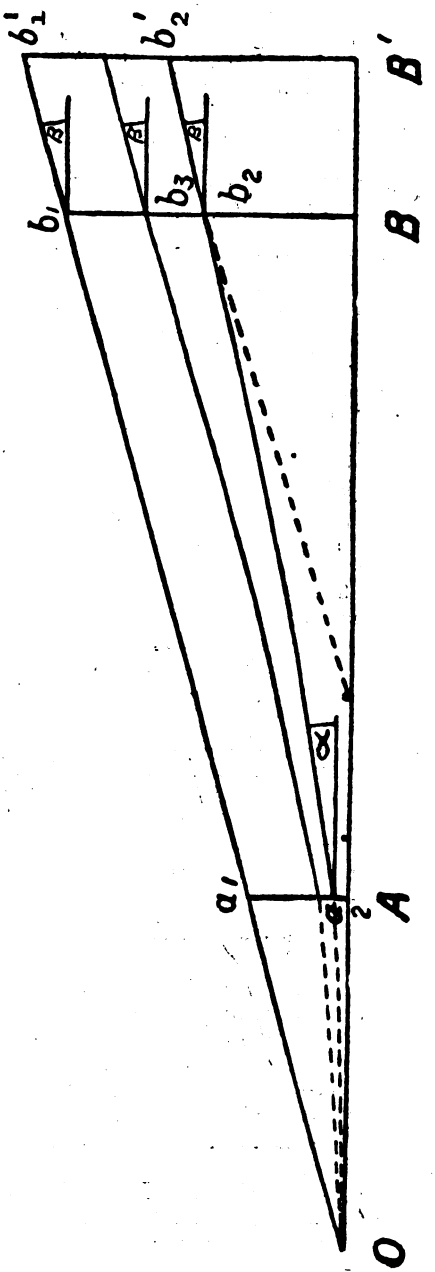

Fig. 1.

Digitized by Google

The shape of the curve of the groove when developed is exhibited in the form and position of the rifling bar of a rifling machine, taking AB to represent the line of axis, and a_1b_1, *or* a_3b_3, the rifling bar or the developed curve of the groove.

The twist of rifling is estimated in artillery as one turn in so many calibres; thus, if the twist is one turn in n calibres, the pitch of the helix, if uniform, is n calibres, or nd inches, if the calibre is d inches; and if β denotes the angle of rifling, that is the angle which the groove makes with the axis,

$$\tan \beta = \frac{\pi d}{nd} = \frac{\pi}{n}.$$

$$\text{Thus, if } \beta = 7^\circ,\ n = \pi \cot \beta = 25{\cdot}6.$$

If the powder pressure and the frictional resistance in the bore are uniform, then the forces producing the rotation are uniform with a uniform twist.

But, as the powder pressure reaches a maximum after a short travel of the projectile, and afterwards rapidly diminishes towards the muzzle, the forces producing rotation on a uniform twist are apt to become excessive at the outset near the breech.

With a view of lessening this excessive stress and of producing more uniformity, the gaining twist was adopted.

The first increasing twist employed was parabolic in its developed form, starting from its vertex O parallel to the axis OAB, and finishing at the muzzle at b_2 at an inclination β, the same as that of the uniform twist, developed into the straight line Ob.

Then, from the property of the parabola, the tangent at b_2, which is parallel to Ob, will pass through the middle point of OB; also, b_2 will be the middle point of Bb_1, so that the projectile will now be turned through only half the angle turned through on the uniform twist, and this was formerly considered an advantage.

It was found, however, that this parabolic twist threw too much strain on the muzzle B, so an intermediate twist was adopted in the 80-ton gun, composed of a curve called the *semi-cubical parabola*, starting from O in the direction of OA, and finishing at b_3 in the direction Ob, such that $Bb_3 = \frac{2}{3}$ Bb, and the tangent at b_3, therefore, passes through the point of trisection of OB, nearest to O.

But now it is considered preferable, when a gaining twist is employed, to take the breech line at a point A instead of O, so that the rifling bar is a_2b_2, starting from a_2 at a certain angle α, with the axis of the bore at AB, or at a certain twist of one turn in m calibres, where m is given by—

$$\tan \alpha = \frac{\pi}{m};$$

and to steady the shot at the muzzle, the muzzle line is moved from B to B′, and the part of the rifling bar from b_2 to b_2' is made straight and parallel to b_1b_1', so that the twist is uniform from B to B′.

Thus, the rifling starts at the breech line A at a twist of one turn in m calibres, and the twist increases up to one turn in n calibres at B, usually on a parabolic twist, although the bar a_2b_2 may be the arc of a circle; and from B to the muzzle B′ the twist is uniform, and one turn in n calibres.

Thus, for instance, the 6-inch Mark I gun is rifled for 65 inches with a twist increasing from one in 120 to one in 35, and continued for the remaining 59 inches to the muzzle on a uniform twist of one in 35.

Digitized by Google

But Sir Andrew Noble has found experimentally that the work lost by the friction of the grooves, and the mean rotating pressure is less with the uniform than with the gaining twist, although the maximum initial forces producing rotation are greater; this is shown by the accompanying Tables (I and II) of results of experiments with a 12-cm. (4·7-inch) gun, firing a 45-lb. projectile with a velocity of 2084 fs, published in the "Proceedings of the Royal Society," vol. 50.

If V denotes the forward axial velocity with which the shot leaves the muzzle, then the spin imparts to the points on the outside cylindrical surface a component velocity at right angles to the axis of magnitude—

$$V \tan \beta = \frac{\pi V}{n} \text{ f/s};$$

this is called the *linear velocity of rotation.*

The *angular velocity of rotation*, in radians/second, is obtained by dividing this by the radius of the shot in feet, a or $d \div 24$; it is, therefore—

$$\frac{\pi V}{nd} \text{ or } \frac{24\pi V}{nd};$$

and this again is converted into revolutions per second by dividing by 2π, since one revolution equals 2π radians; the shot, therefore, makes—

$$\frac{V}{2nd} \text{ or } \frac{12V}{nd} \text{ revs/sec.}$$

Thus, comparing the 6-inch gun and magazine rifle, in each of which $n = 30$; then for the same muzzle velocity, say 2000 f/s, the linear velocities of rotation will be the same, namely 209 f/s, but the rifle bullet will make 2640 revs/second, against 133 revs/second of the 6-inch projectile.

Formerly it was considered requisite for a projectile to possess a given linear velocity of rotation to ensure its stability in flight, and for this reason the twist of rifling in howitzers, firing with low velocities, was made very quick, even up to one in 12 calibres.

But, it is now found that the linear velocity of rotation should be a given fraction of the initial velocity, so that the same twist of rifling is suitable for high or low velocities, with a given projectile; but the determination of the appropriate twist from theoretical considerations is not a simple matter, and the twist must be settled by experiment to a great extent.

The investigation of the stability of an elongated projectile moving through the air in the direction of its axis with given angular velocity is very similar to that required for the stability of a top or gyrostat, spinning with its axis vertical, and the behaviour of the bodies have a close analogy. The annexed Table shows the result of such calculations.

When a top is spun, the motion of the axis is at first unsteady, but this unsteadiness soon disappears, and the top then spins upright, when it is said to go to sleep; after a time the friction of the point reduces the spin to such an extent that the vertical position becomes unstable, and the axis again begins to wobble; the axis inclines more and more from the upright position, until finally the top falls over on its side.

So, too, an elongated projectile fired from a rifled gun is at first rather unsteady from the first portion of its flight, but the friction of the air soon destroys the irregular gyrations, and the shot, if provided with sufficient spin, proceeds steadily in the direction of the axis.

If the spin of the projectile died away more rapidly than the forward velocity, the projectile, like the top, would again become unsteady.

But the forward retardation of the shot is much greater than the angular retardation, so that the shot moves as if on an increasing screw; and practically, if once steady, the shot will continue so throughout its trajectory, in consequence of this *overscrew*.

In high angle fire, however, the motion tends to become unsteady in the descending branch, in consequence of the great curvature of the trajectory.

Drift.

This is an effect observable with all rifled guns, by which the shot is deflected in its flight more or less from the vertical plane of fire; the deflection is to the right when the gun is rifled with a twist on a right-handed screw, to the left with a left-handed twist.

Thus it was found by Mr. Rigby, Superintendent R.S.A.F., Enfield, that with two barrels rifled with right- and left-handed twists, and laid parallel, the bullets struck on a target at 1000 yards on an average 15 inches farther apart than the muzzles, showing that the *drift* of the rifle bullet at this range is about $7\frac{1}{2}$ inches.

The drift increases rapidly with the elevation and range of the gun; thus it was found that the 9·2-inch fired at Shoeburyness with an elevation of 40° and a muzzle velocity of 2375 f/s, sent a shot weighing 380 lbs. to a range of 20,000 yards, and that the drift was about 1,000 yards to the right of the vertical plane of fire.

Disregarding theories and explanations, the established facts connected with drift are as follows:—With service projectiles having pointed heads and right-handed rotation, the drift is to the right; other things remaining unchanged, it is found that the greater the twist the greater the drift; the smooth and well-centred B.L. projectiles drift less than the M.L. shells, which are roughened by studs; at extreme ranges the drift always increases rapidly, and the projectile becomes unsteady in flight, owing to the greater curvature of the trajectory.

The minor effects of the resistance of the air and of the rotation of the projectile cause the axis of the latter to remain with the axis of the shot nearly tangential to the trajectory, but with the point of the projectile a little above and to the right of the vertical plane of fire; this is verified from the fact that the holes made in wooden targets are as nearly as possible circular, even when the angle of descent is considerable, and also from watching by eye the behaviour of projectiles fired with low velocities (500—600 f/s) at considerable elevations (50—70°).

Wind Deflection.

To begin with, elongated rifled projectiles will not be considered; the elementary case of a spherical ball projected from a smooth bore gun into a cross wind will be taken instead.

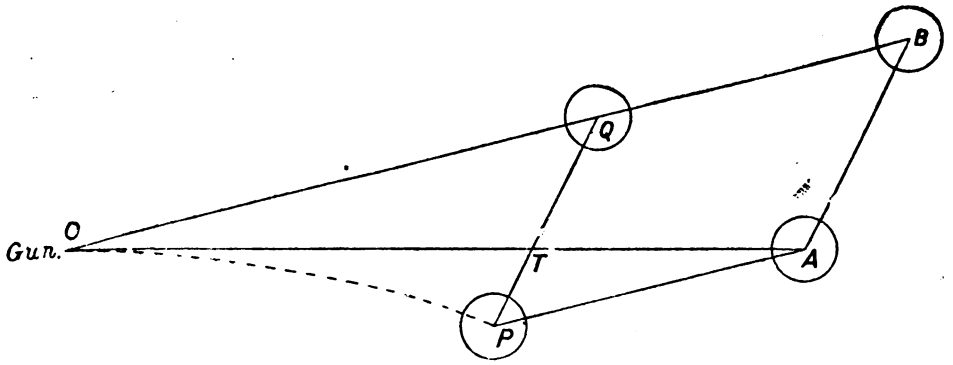
In the first place, assume that there is no gravity, no air resistance and no wind, then the velocity V f/s will carry the shot from the muzzle O in the time of flight t to A in a straight line $OA = Vt$.

Now suppose there is a wind shown by the weathercock, in the direction BA of velocity W f/s; measure off $AB = Wt$; then OB

Digitized by Google

will be the direction of the shot *through the air;* and, with respect to the air, the shot will have reached the point B in the air in the time t.

Fig. 2.



But air always offers a resistance; so, suppose that in t secs. the shot has moved through the air a distance OQ, less than OB. Draw QP equal and parallel to BA; then QP is the "air drift" in the time t, so that the shot will be found at a point P over the ground and TP is the deviation due to the wind.

The path of the shot over the ground is now a curved track OP, shown by the dotted line.

The wind deflection TP at a range OT of R yards or 3R feet is thus,

$$\begin{aligned} TP = AB - TQ &= AB\left(1 - \frac{TQ}{AB}\right), \\ &= AB\left(1 - \frac{OT}{OA}\right), \\ &= Wt\left(1 - \frac{3R}{Vt}\right) = W\left(t - \frac{3R}{V}\right), \\ &= W(t - T), \end{aligned}$$

where $T = \frac{3R}{V}$ is the time of flight over the range R yards with undiminished velocity V; $t - T$ may be called the lag or "air delay" over the range; so that the wind deflection is the same as the air drift during the delay $t - T$. This delay is large when the retardation of the shot is large in consequence of the smallness of the ballistic coefficient, as in small arm bullets; the delay diminishes as the ballistic coefficient increases with the size of the gun in artillery fire; the delay would be zero, and the wind deflection zero also in a gun with very large ballistic coefficient.

So far, a round shot only has been considered; this experiences the same resistance whichever way it is projected.

When an elongated projectile is projected over the ground with its axis along OA, then relatively to the air it is projected with an additional broadside velocity due to the wind.

Digitized by Google

In consequence of this broadside motion the shot will perform gyrations in the air round the line OB due to the spin imparted by the rifling. These gyrations die out rapidly from the frictional damping of the air, and with appropriate rifling the shot soon settles down to a steady progression through the air in the direction OB, so the theory for a round shot is equally applicable to an elongated projectile fired from a rifled gun.

With a wind across the range the deflection TP is lateral, and the alteration of range from OT to OP is practically insensible and no alteration of sighting elevation is required.

But with a wind very nearly up or down the range, the deflection TP is chiefly in range, so that an additional investigation is required of the motion of the shot in a vertical plane, and of the alteration in elevation required to correct the error in range TP, or height of impact on a vertical target; the investigation of this is reserved for Part II.

EXAMPLES.

Calculate the lateral effect of a wind of 20 f/s blowing in a direction which makes an angle of 30° with the line of fire, at a range of 2,000 yards; of

(i) a 6-inch B.L. gun, C = 3·00, V = 2000 f/s.
(ii) a 0·303 rifle, C = 0·417, V = 2000 f/s.

The velocity of the wind directly across the line of fire is

$$20 \times \sin 30° = 10 \text{ f/s},$$

so that here

$$W = 10.$$

Employing the formula

$$\text{Deflection} = W\left(t - \frac{3R}{V}\right) \text{ feet},$$

we find t from the formulæ

$$S_s = S_V - \frac{3R}{C},$$

$$t = C\,(T_V - T_s),$$

using Bashforth's tables.

V = 2000 f/s.	i.	ii.
s	6000 feet	6000 feet
$\frac{s}{C}$	2000	14390
S_{2000}	45207·1	45207·1
S_s	43207·1	30817·1
v	1510	569

Digitized by Google

$V = 2000$ f/s.	i.	ii.
T_{2000}	233·4956	233·4956
T_v	232·3424	217·2953
$\frac{t}{C}$	1·1532	16·2003
t	3·46	6·754
$3R/V$	3·00	3·00
$W\left(t - \frac{3R}{V}\right)$	4·6 feet	37·54 feet,

so that the deflection amounts to

$4\frac{1}{2}$ feet for the 6-inch projectile,

$37\frac{1}{2}$ feet for the ·303 bullet.

Table II.

Showing the Resistance of the Air in pounds (p) to a 1-inch Projectile with an Ogival head of $1\frac{1}{2}$ diameters radius under standard conditions of shape, steadiness, and density of air, for velocities from 100 to 2800 f/s.

Calculated by Mr. A. G. Hadcock, late R.A., from Mr. Bashforth's values of K, by the use of the formula

$$p = \frac{K}{g}\left(\frac{v}{1000}\right)^3 = \frac{k}{g}\left(\frac{v}{1000}\right)^2.$$

Table III.

Time t in seconds, between velocities V and v f/s,

$$t = C\,(T_V - T_v).$$

(From Supplement *Bashforth's Motion of Projectiles*, 1881.)

Table V.

Deviation δ in degrees, between velocities V and v f/s.

$$\delta = C\,(D_V - D_v).$$

(By W. D. Niven, F.R.S.)

Table IX.

Ballistic Table for Spherical Shot.

(Recalculated by Mr. Hadcock, R.A., from Bashforth's data, and extended to low velocities.)

For lower velocities this table is provisional, pending the results of further experiments.

Table XI.

Tenuity correction τ for Temperature and Pressure of Atmosphere two-thirds saturated with Moisture.

(From the Rev. F. Bashforth's paper, *Proc. R.A.I.*, Vol. XIII, No. 10.)

TABLE XII.

Conversion of Measures.

(Chiefly based on data contained in Col. Noble's Useful Tables.)

Length.

Metric to British.

Metres.	Yards.	Feet	Inches.
1	1·0936	3·2809	39·37
2	2·1873	6·5618	78·74
3	3·2809	9·8427	118·11
4	4·3745	13·1236	157·48
5	5·4682	16·4045	196·85
6	6·5618	19·6854	236·22
7	7·6554	22·9663	275·60
8	8·7491	26·2472	314·97
9	9·8427	29·5281	354·34

British to Metric.

Yds.	Mètres	Ft.	Mètres.	Ins.	Centimètres.
1	0·91438	1	0·30479	1	2·5400
2	1·82877	2	0·60959	2	5·0799
3	2·74315	3	0·91438	3	7·6199
4	3·65753	4	1·21918	4	10·1598
5	4·57192	5	1·52397	5	12·6998
6	5·48630	6	1·82877	6	15·2397
7	6·40068	7	2·13356	7	17·7797
8	7·31507	8	2·43836	8	20·3196
9	8·22945	9	2·74315	9	22·8596

Metric Table of Length.

Millimètres.
10 = 1 centimètre.
100 = 1 décimètre,
1000 = 1 mètre.
Mètres.
10 = 1 décamètre.
100 = 1 hectomètre.
1000 = 1 kilomètre.

EXPLANATION.—To convert any number from one measure to the other, take the values of the different multiples of 10 by shifting the position of the decimal point, and add together. Thus, find the number

of yards in 2354 mètres (see cols. 1 and 2)	of feet in 12·4 mètres (see cols. 1 and 3).	of inches in 30·5 centimètres (see cols. 1 and 4). Note, 1 m. = 100 cm.	of mètres in 1026 yards (see cols. 5 and 6).	of mètres in 1742 feet (see cols. 7 and 8).	of centimètres in 17·72 ins. (see cols. 9 and 10).
mètres. yards.	mètres. feet.	cms. inches.	yards. mètres.	feet. mètres.	inches. cms.
2000 = 2187·3	10 = 32·809	30·0 = 11·811	1000 = 914·38	1000 = 304·79	10 = 25·400
300 = 328·09	2 = 6·562	·5 = 0·197	20 = 18·29	700 = 213·36	7 = 17·780
50 = 54·68	0·4 = 1·312		6 = 5·49	40 = 12·19	0·7 = 1·778
4 = 4·37				2 = 0·61	0·02 = 0·051
∴ 2354 = 2574·44	∴ 12·4 = 40·683	∴ 30·5 = 12·008	∴ 1026 = 938·16	∴ 1742 = 530·95	∴ 17·72 = 45·009

NOTE.—If a table of conversion is not at hand, an approximation to the equivalent in inches of a distance measured in centimètres may be obtained by multiplying by 0·4: thus, 30·5 cm. multiply by 0·4, and we have 12·2 inches; the real equivalent as shown above is 12·008 inches.

Weight.

Metric to British.

Kilogrammes.	Tons.	Pounds Avoirdupois.	Grains Troy.
1	·000984	2·2046	15432·3
2	·001968	4·4092	30864·7
3	·002953	6·6139	46297·0
4	003937	8·8185	61729·4
5	·004921	11·0231	77161·7
6	·005905	13·2277	92594·1
7	·006889	15·4323	108026·4
8	·007874	17·6370	123458·8
9	·008858	19·8416	138891·1

British to Metric.

Tons.	Metric tons or milliers	Pounds Avoirdupois.	Kilogrammes	Grains Troy.	Grammes.
1	1·016	1	0·4536	1	·0648
2	2·032	2	0·9072	2	·1296
3	3·048	3	1·3608	3	·1944
4	4·064	4	1·8144	4	·2592
5	5·080	5	2·2680	5	·3240
6	6·096	6	2·7216	6	·3888
7	7·112	7	3·1751	7	·4536
8	8·128	8	3·6287	8	·5184
9	9·144	9	4·0823	9	·5832

Metric Table of Weight.

Milligrammes.
10 = 1 centigramme.
100 = 1 décigramme.
1000 = 1 gramme.
Grammes.
10 = 1 décagramme.
100 = 1 hectogramme.
1000 = 1 kilogramme.
Kilogrammes.
10 = 1 myriagramme.
100 = 1 quintal.
1000 = 1 millier, or tonne, or metric ton.

EXPLANATION.—To convert any number from one measure to the other, take the values of the different multiples of 10 by shifting the position of the decimal point, and add together. Thus, find the number

of tons in 35 tonnes. (see cols. 1 and 2).	of pounds in 56·3 kgms. (see cols. 1 and 3).	of grains in 120 grammes (see cols. 1 and 4).	of tonnes in 38 tons. (see cols. 5 and 6).	of kilogrammes in 68 pounds. (see cols. 7 and 8).	of grammes in 85 grains. (see cols. 9 and 10)
tonnes. tons.	kgms. lbs.	grammes. grains.	tons. tonnes.	lbs. kgs.	grains. grammes
30 = 29·53	50 = 110·231	100 = 1543·23	30 = 30·48	60 = 27·216	80 = 5·184
5 = 4·92	6 = 13·228	20 = 308·65	8 = 8·13	8 = 3·629	5 = 0·324
∴ 35 = 34·45	∴ 56·3 = 124·120	∴ 120 = 1851·88	∴ 38 = 38·61	∴ 68 = 30·845	∴ 85 = 5·508

NOTE.—7000 grains troy = 1 pound avoirdupois.

TABLE XII—*continued.*

Pressure.

Metric and Atmospheric to British.

Kilogrammes per sq. cm.	Pounds per square inch.	Tons per square inch.	Atmospheres.	Pounds per square inch.	Tons per square inch.
1	14·223	·00635	1	14·7	·00656
2	28·446	·01270	2	29·4	·01313
3	42·668	·01905	3	44·1	·01969
4	56·891	·02540	4	58·8	·02625
5	71·114	·03175	5	73·5	·03281
6	85·337	·03810	6	88·2	·03938
7	99·560	·04445	7	102·9	·04594
8	113·783	·05080	8	117·6	·05250
9	128·005	·05715	9	132·3	·05906

British to Metric and Atmospheric.

Pounds per square inch.	Kilogrammes per sq. cm.	Atmospheres.	Tons per square inch.	Kilogrammes per sq. cm.	Atmospheres.
1	·07031	·068	1	157·49	152·38
2	·14062	·136	2	314·99	304·76
3	·21093	·204	3	472·48	457·14
4	·28124	·272	4	629·97	609·52
5	·35155	·340	5	787·47	761·91
6	·42186	·408	6	944·96	914·29
7	·49217	·476	7	1102·45	1066·67
8	·56248	·544	8	1259·95	1219·05
9	·63279	·612	9	1417·44	1371·43

EXPLANATION.—To convert any number from one measure to the other, take the values of the different multiples of 10 by shifting the position of the decimal point, and add together. Thus, find the number

of pounds per square inch in 32·1 kilogrammes per square centimètre (see cols. 1 and 2). kgs. per sq. cm.	lbs. per sq in.
30	= 426·68
2	= 28·45
0·1	= 1·42
32·1	= 456·55

of tons per square inch in 3210 kilogrammes per square centimètre (see cols. 1 and 3). kgs. per sq. cm.	tons per sq. in.
3000	= 19·05
200	= 1·27
10	= 0·06
∴ 3210	= 20·38

of tons per square inch in 3254 atmospheres (see cols. 4 and 6). atmospheres.	tons per sq. in.
3000	= 19·69
200	= 1·31
50	= 0·33
4	= 0·03
∴ 3254	= 21·36

of kilogrammes per square centimètre in 15 lbs. on the square inch (see cols. 7 and 8). lbs. per sq. in.	kgs. per sq. cm.
10	= 0·7031
5	= 0·3516
∴ 15	= 1·0547

of kilogrammes per square centimètre in 18·3 tons per square inch (see cols. 10 and 11). tons per sq. in.	kgs. per sq. cm.
10	= 1574·9
8	= 1259·95
0·3	= 47·25
∴ 18·3	= 2882·1.

of atmospheres in 14·6 tons per square inch (see cols. 10 and 12) tons per sq. in.	atmospheres.
10	= 1523·8
4	= 609·5
0·6	= 91·4
∴ 14·6	= 2224·7

Energy.

Metric to British.

Mètre-tons.	Foot-tons
1	3·2291
2	6·4581
3	9·6872
4	12·9162
5	16·1453
6	19·3743
7	22·6034
8	25·8324
9	29·0615

British to Metric.

Foot-tons.	Mètre tons.
1	0·3097
2	0·6194
3	0·9291
4	1·2388
5	1·5484
6	1·8581
7	2·1678
8	2·4775
9	2·7872

EXPLANATION.—To convert any number from one measure to the other, take the values of the different multiples of 10 by shifting the position of the decimal point, and add together. Thus, find the number

of foot-tons in 4367 mètre-tonnes (see cols. 1 and 2) mètre-tonnes.	foot-tons.
4000	= 12916·2
300	= 968·72
60	= 193·74
7	= 22·60
∴ 4367	= 14101·26

of mètre-tonnes in 3592 foot-tons (see cols. 3 and 4). foot-tons.	mètre-tonnes.
3000	= 929·1
500	= 154·84
90	= 27·87
2	= 0·62
∴ 3592	= 1112·43

NOTE.—1000 mètre-tons is called a dinamode in Italy.

APPENDIX.

ARMOUR.

Armour may be divided into three classes: hard, soft, and hard-faced.

Hard Armour.

The main representative of this class is chilled cast-iron which has been largely used on the Continent, mainly on sea fronts, in the form of cupolas, It cannot be perforated in the strict sense of the term, but must be broken up. Fracture appears to depend upon some function of the striking energy of the attacking projectile, but to be independent of its diameter. Even when capable of withstanding one or two blows from the larger natures of projectile, chilled iron is apt to crumble under the continuous bombardment of steel armour-piercing projectiles from guns of medium calibre.

Soft Armour.

Wrought-iron and mild steel belong to this class. They can be perforated, but do not easily break up, though steel has a greater tendency in this direction than wrought-iron. Perforation appears to be directly proportional to some powers of the weight and striking velocity of an attacking projectile, and to be inversely proportional to some power of its diameter.

Wrought-iron armour is only to be found in a few old ships, in old-fashioned coast defences, and possibly in some inland forts.

A considerable amount of steel armour of the soft class is still to be found in permanent works on land and to a less extent in ships.

Hard-Faced Armour.

Compound armour is the earliest armour of this class. In it an attempt was made to combine the advantages of both the foregoing classes by welding a hard steel face on to a wrought-iron foundation plate, thus combining a tough body to hold the plate together with a surface hard enough to break up an attacking projectile.

A rigid backing was necessary to bring out fully the good qualities of compound plates, and when insufficiently supported they were probably not the equal of the best steel plates.

Both compound and ordinary steel armour were superseded in 1891 by steel plates made by the Harvey process, which consisted mainly in carburizing, or cementing as it is usually termed, the surface of a suitable steel plate, the carburized surface being subsequently chilled by jets of cold water according to the method invented by Capt. T. J. Tresidder, C.M.G., late R.E. In this way a plate was obtained which possessed in a very high degree the special merits of compound armour without the great defect of the latter—a tendency for the hard steel surface plate to crack and become detached from the iron foundation plate.

Digitized by Google

Since 1893 considerable improvements, in great measure due to the firm of Krupp, of Essen, have been effected in the composition of armour plate steel and also in its treatment during manufacture.

Special steel alloys containing from 3 to 4 °/₀ of nickel and from 1 to 2 °/₀ of chromium, in addition to small percentages of manganese and carbon, which are very much harder and tougher than ordinary steel, are employed, and the plates made from this material undergo a very elaborate heat treatment during manufacture and before the final chilling.

Both cemented and uncemented plates of the Krupp type are made, the latter being largely used when armour of less than 4 inches is required and, in some cases, for curved structures of greater thickness.

The composition of the non-cemented plates differs little, if at all, from that of the cemented plates, and the process of manufacture is also similar, except as regards cementation.

Armour of the hard-faced class to which all the above belong (the K.N.C. plates, although not superficially carburized, have extremely hard surfaces) is intermediate in character between hard and soft armour. The manner in which it yields when attacked is discussed below.

Armour-Piercing Projectiles.

Armour-piercing shot are no longer made for the British service, and capped shell which have a bursting charge capacity of at least 2 °/₀ of the total weight of the projectile are the only armour-piercing projectiles to be manufactured in future.

The steel of which these shell are made is an alloy, the composition of which varies with the manufacturer, but which in addition to carbon usually contains chromium combined with one or more of the following elements: nickel, manganese, tungsten, molybdenum.

The cap, which is of mild steel, weighing from 5 to 2½ °/₀ of the weight of the shell, varies in shape according to the manufacturer and is attached to the point of the projectile in various ways, a common method being to press it hydraulically or otherwise into notches or grooves in the head of the shell. Its function is to support the point of the projectile when the latter strikes the plate and so enable it to get unbroken through the hard surface layer of Harveyed or Krupped plates. It would probably not be of any assistance in attacking soft armour, and to be thoroughly effective, the projectile must be strong enough to remain intact until perforation has been accomplished.

The cap does not appear to be effective below a striking velocity of about 1700 f/s. or outside an angle of about 30° to the normal, and beyond these limits the action of a capped A.P. projectile does not differ from that of an uncapped one.

Boring and Punching.

When an uncapped projectile or an A.P. projectile below the velocity referred to above strikes a hard-faced plate, its head is crushed and driven back into the body of the projectile, breaking it up, and the tendency of its action on the plate is to punch out a coned disc, the base of the cone being at the back of the plate. The maximum diameter of the disc is frequently more than three times that of the attacking projectile, the disproportion being most marked when the diameter of the projectile is considerably in excess of the thickness of the plate.

Digitized by Google

When, on the other hand, a capped A.P. projectile strikes a hard-faced plate with sufficient velocity, the cap has the effect of holding the point of the projectile together until it has penetrated the hard surface layers. The projectile can then perform its proper work as a boring tool, and if it has sufficient energy to get through the plate, drills a hole in it of approximately the same diameter as itself. Less energy is required to perforate than to punch, and consequently an A.P. projectile can get through a plate at a very much lower velocity capped than uncapped. Occasionally the action of a capped projectile in perforating a plate is not truly a boring one but a more or less cylindrical plug of metal of approximately the same diameter as the shot is punched out. In such cases the point of the projectile will usually be found blunted or broken off from the body, indicating that full benefit has not been received from the cap.

In the case of punching it is found that the resisting value of a plate falls off in proportion as the diameter of the attacking projectile exceeds the thickness of the plate. For instance, a 6″ K.C. plate may have a figure of merit (value compared to wrought-iron) of 2·6 against a 6″, but not more than 2·2 against a 9·2″ uncapped shot. In the case of perforation, however, there is some reason to think that the advantage is relatively with projectiles of smaller diameter than the thickness of the plate attacked, though the difference is not very marked; thus a plate whose figure of merit against a capped projectile of its own calibre is, say, 2·2, may have a figure of merit of not more than 2 against a projectile of less diameter than its own thickness.

The figure of merit of Harveyed or Krupped armour varies also with its thickness, being at a maximum when the plate is about 6″ thick, falling off above and, possibly, below this point.

Roughly speaking, the following table gives the comparative values of various kinds of armour against uncapped A.P. shot of calibre equivalent to the thickness of the plate or similar capped A.P. projectiles with striking velocity below about 1700 f/s. :—

Wrought-iron	1·0
Mild steel	1·3
Compound...	1·3
Harveyed steel (up to 1897) ...	1·7 to 2·2 according to thickness
Krupp non-cemented steel (K.N.C.) or Harveyed steel since 1897 ...	2·1 to 2·4 „ „ „
Krupp cemented steel (K.C.) ...	2·3 to 2·7 „ „ „

Against capped A.P. projectiles, with striking velocities of 1700 f/s. and over, the figure of merit of K.C. plates is approximately 2 0.

The penetrative power of uncapped A.P. and common shell may be taken as roughly 0·8 and 0·6 times, respectively, that of uncapped A.P. shot.

On the continent the figure of merit referred to above is not employed and the various classes and thicknesses of armour are compared by finding "R," the ratio between the velocity required for the actual perforation of any given plate and that required for the perforation of mild steel of the same thickness, by de Marre's formula given below.

Digitized by Google

A.P. Formulas.

These are for the most part empirical.

Leaving on one side the case of hard armour, whose fracture seems to depend on the striking energy only of the projectile and to be independent of its diameter, *vide* p. 36 "Armour and its attack by Artillery," by Capt. C. Orde Browne, late R.A., it is generally agreed that both perforation and punching vary directly as some powers of the weight and velocity of the projectile and inversely as some power of its diameter.

Assuming the formula to be monomial, the simplest method of determining these exponents is by means of a logarithmic chart.

If, for example, it is desired to obtain a monomial formula for the perforation of K.C. armour by capped A.P. shell, actual results obtained by firing any particular calibre of gun against varying thicknesses of plate should be plotted on a logarithmic chart, so that the horizontal co-ordinates represent velocities (v), and the vertical components represent thicknesses (t), of plate just perforable at those velocities. The co-ordinates will thus represent not the quantities in question but their logarithms.

If now a straight line can be drawn through the points so obtained the equation to the curve is monomial, and from the lengths of the co-ordinates we can determine the exponents of t and v.

Thus, if the horizontal co-ordinate (v) is 40 mm. in length and the vertical (t) is 80 mm., we know that $t \propto v^2$. Similar results with other calibres of gun should also be plotted and if a straight line can be drawn through the points so obtained, parallel to that first determined, we know that the relation between t and v holds for both calibres of projectile and probably for all others of the same type.

By similar means we can obtain the relation between any other pair of variables; thus, the striking energy may be kept constant and the relation between t and d determined.

The constants, which must be obtained by calculation, may or may not be the same for all calibres.

If, however, it is ascertained that approximately the same constant holds in each case, we will have obtained an empirical formula

$$v^n = \frac{t^x\, d^y}{w^z}\, \mathrm{K}.$$

Some formulas, however, such as Tresidder's formula for the perforation of wrought-iron, apart from the constant, have been constructed from purely theoretical considerations and have been found to give results in accordance with actual experiment.

The following formulas are useful.

They are given in both English and metric units, the following being the notations employed:—

English.	Metric.
v = striking velocity in feet per second.	v = striking velocity in metres per second.
t = normal thickness of plate in inches.	e = normal thickness of plate in centimetres.
d = diameter of projectile in inches.	a = diameter of projectile in centimetres.
w = weight of projectile in pounds.	p = weight of projectile in kilogrammes.

Digitized by Google

Name of formula.	Armour.	English Units.	Metric Units.
Tresidder	Wrought iron ..	$v^3 = \frac{t^2 d}{w} \times \log^{-1} 8{\cdot}8410$	$v^3 = \frac{e^2 a}{p} \times \log^{-1} 5{\cdot}7352$
de Marre	Mild steel ..	$v = \frac{t^{0{\cdot}7} d^{0{\cdot}75}}{w^{0{\cdot}5}} \times \log^{-1} 3{\cdot}0094$	$v = \frac{e^{0{\cdot}7} \times a^{0{\cdot}75}}{p^{0{\cdot}5}} \times \log^{-1} 1{\cdot}7347$
Davis ..	Harveyed steel (1899 and 1900)	$v^2 = \frac{t^{1{\cdot}5} d}{w} \times \log^{-1} 6{\cdot}6900$	$v^2 = \frac{e^{1{\cdot}5} a}{p} \times \log^{-1} 4{\cdot}3026$
Krupp ..	Krupp cemented (K.C.) steel ..	$v^2 = \frac{t^2 d}{w} \times \log^{-1} 6{\cdot}3532$	$v^2 = \frac{e^2 a}{p} \times \log^{-1} 3{\cdot}7634$
A Russian (Vickers)	Krupp cemented (K.C.) steel ..	$v^2 = \frac{t^{1{\cdot}4} d^{1{\cdot}5}}{w} \times \log^{-1} 6{\cdot}3954$	$v^2 = \frac{e^{1{\cdot}4} a^{1{\cdot}5}}{p} \times \log^{-1} 3{\cdot}8460$

All the above formulas are for uncapped A.P. shot striking normally.

For oblique impact up to 30°, substitute $t \sec \theta$ for t, θ being the angle of incidence.

A very fairly accurate rough rule for arriving at the thickness of Krupp armour perforable by uncapped A.P. shot (under service conditions, *i.e.*, with striking velocity less than 2000 f/s.), may be obtained by reducing the formula given above to a simpler form.

Divide each side of the equation $t^2 = \frac{wv^2}{d} \times \frac{1}{\log^{-1} 6{\cdot}3532}$ by d^2 and we get

$$\frac{t^2}{d^2} = \frac{w}{d^3} v^2 \times \frac{1}{\log^{-1} 6{\cdot}3532}.$$

Now make $\frac{w}{d^3}$ constant and $= 0{\cdot}46$ and we obtain, on simplifying, $\frac{t}{d} = \frac{v}{2200}$, which is about right for 6″ projectiles against a 6″ K.C. plate and gives a margin in favour of the gun in the case of the larger calibres.

There is no generally accepted formula for capped A.P. shot against Krupped or Harveyed plates, though Davis' formula

$$t^{1{\cdot}6} = \frac{wv^2}{d} \times \frac{1}{\log^{-1} 6{\cdot}5061}$$ has been used in America.

A fairly satisfactory rough rule within the ordinary range of striking velocities is $\frac{t}{d} = \frac{v}{1950}$.

In all cases, however, either for capped or uncapped projectiles, it will be found more satisfactory to use Tresidder's wrought-iron formula in conjunction with a suitable figure of merit.

Examples:—

(1) What thickness of K.C. armour would you expect an uncapped 6″ A.P. shell (w = 100 lbs.) to perforate with striking velocities of 1600 f/s. and 2300 f/s.? Use Krupp's K.C. formula and assume that an uncapped A.P. shell has five-sixth the penetrative power of an uncapped A.P. shot.

v.	1600.	2300.
$\log v$	3·2041	3·3617
$2 \log v$	6·4082	6·7234
$\log w$	2·0000	2·0000
$k = \log (\log^{-1} \bar{7}\cdot6469)$	$\bar{7}\cdot6469$	$\bar{7}\cdot6469$
$\log wv^2k$	2·0551	2·3703
$\log d$	0·7782	0·7782
$\log t_1^2$	1·2769	1·5921
$\log t_1$	0·6384	0·7960
t_1	4·35	6·25
t	3·63	5·21

(2) At what ranges will capped 9·2″ (w = 380 lbs.) and 7·5″ (w = 200 lbs.) A.P. shell get through a 7″ K.C. plate respectively? Take the muzzle velocity in each case as 2750 f/s.

Answer—

9·2″ ... 6,000 yards approximately.
7·5″ ... 4,000 „ „

(3) What figures of merit are implied in the answers to example (2)?
